

1000 Examples programming in

Python

1000 Python Examples

Gábor Szabó

This book is for sale at <http://leanpub.com/python-examples>

This version was published on 2020-05-28

This is a [Leanpub](#) book. Leanpub empowers authors and publishers with the Lean Publishing process. [Lean Publishing](#) is the act of publishing an in-progress ebook using lightweight tools and many iterations to get reader feedback, pivot until you have the right book and build traction once you do.

© 2020 Gábor Szabó

Contents

First steps	1
What is Python?	1
What is needed to write a program?	1
The source (code) of Python	2
Python 2 vs. Python 3	2
Installation	2
Installation on Linux	3
Installation on Apple Mac OSX	3
Installation on MS Windows	3
Editors, IDEs	4
Documentation	6
Program types	6
Python on the command line	6
First script - hello world	7
Examples	7
Comments	7
Variables	8
Exercise: Hello world	8
What is programming?	8
What are the programming languages	8
A written human language	9
A programming language	9
Words and punctuation matter!	9
Literals, Value Types in Python	9
Floating point limitation	10
Value Types in Numpy	10
Rectangular (numerical operations)	11
Multiply string	11
Add numbers	11
Add strings	11
Exercise: Calculations	11
Solution: Calculations	12
Second steps	13

CONTENTS

Modules	13
A main function	13
The main function - called	13
Indentation	14
Conditional main	14
Input - Output I/O	15
print in Python 2	15
print in Python 3	16
print in Python 2 as if it was Python 3	17
Exception: SyntaxError: Missing parentheses in call	17
Prompting for user input in Python 2	17
Prompting for user input in Python 3	18
Python2 input or raw_input?	19
Prompting both Python 2 and Python 3	19
Add numbers entered by the user (oups)	20
Add numbers entered by the user (fixed)	20
How can I check if a string can be converted to a number?	21
Converting string to int	21
Converting float to int	22
Conditionals: if	23
Conditionals: if - else	23
Conditionals: if - else (other example)	24
Conditionals: else if	24
Conditionals: elif	25
Ternary operator	25
Case or Switch in Python	26
Exercise: Rectangular	26
Exercise: Calculator	26
Exercise: Standard Input	26
Solution: Area of rectangular	26
Solution: Calculator	28
Command line arguments	29
Command line arguments - len	29
Command line arguments - exit	30
Exercise: Rectangular (argv)	30
Exercise: Calculator (argv)	30
Solution: Area of rectangular (argv)	30
Solution: Calculator eval	31
Solution: Calculator (argv)	32
Compilation vs. Interpretation	33
Is Python compiled or interpreted?	33
Flake8 checking	34

CONTENTS

Numbers	35
Numbers	35
Operators for Numbers	35
Integer division and the future	36
Pseudo Random Number	37
Fixed random numbers	37
Rolling dice - randrange	38
Random choice	38
built-in method	38
Exception: TypeError: 'module' object is not callable	39
Fixing the previous code	39
Exception: AttributeError: module 'random' has no attribute	40
Exercise: Number guessing game - level 0	41
Exercise: Fruit salad	41
Solution: Number guessing game - level 0	41
Solution: Fruit salad	41
Boolean	43
if statement again	43
True and False	43
Boolean	44
True and False values in Python	44
Comparison operators	45
Do NOT Compare different types	45
Boolean operators	46
Boolean truth tables	47
Short circuit	47
Short circuit fixed	48
Incorrect use of conditions	48
Exercise: compare numbers	49
Exercise: compare strings	49
Solution: compare numbers	50
Solution: compare strings	50
Strings	52
Single quoted and double quoted strings	52
Long lines	52
Triple quoted strings (multiline)	53
String length (len)	54
String repetition and concatenation	54
A character in a string	55
String slice (instead of substr)	55
Change a string	55

CONTENTS

How to change a string	56
String copy	56
String functions and methods (len, upper, lower)	57
index in string	57
index in string with range	58
rindex in string with range	58
find in string	59
Find all in the string	59
in string	60
index if in string	60
Encodings: ASCII, Windows-1255, Unicode	60
raw strings	61
ord	61
ord in a file	62
chr - number to character	62
Exercise: one string in another string	64
Exercise: to ASCII CLI	64
Exercise: from ASCII CLI	65
Solution: one string in another string	65
Solution: compare strings	65
Solution: to ASCII CLI	65
Solution: from ASCII CLI	66
Loops	67
Loops: for-in and while	67
for-in loop on strings	67
for-in loop on list	67
for-in loop on range	68
Iterable, iterator	68
for in loop with early end using break	68
for in loop skipping parts using continue	68
for in loop with break and continue	69
while loop	69
Infinite while loop	70
While with complex expression	71
While with break	71
While True	72
Duplicate input call	72
Eliminate duplicate input call	72
do while loop	72
while with many continue calls	73
Break out from multi-level loops	73
Exit vs return vs break and continue	73

CONTENTS

Exercise: Print all the locations in a string	74
Exercise: Number guessing game	74
Exercise: MasterMind	75
Exercise: Count unique characters	75
Solution: Print all the locations in a string	75
Solution 1 for Number Guessing	75
Solution for Number Guessing (debug)	76
Solution for Number Guessing (move)	77
Solution for Number Guessing (multi-game)	78
Solution: MasterMind	79
Solution: Count unique characters	80
MasterMind to debug	81
PyCharm	84
PyCharm Intro	84
PyCharm Project	84
PyCharm Files	84
PyCharm - run code	84
PyCharm Python console at the bottom left	84
Refactoring example (with and without pycharm)	85
Formatted printing	86
format - sprintf	86
Examples using format - indexing	86
Examples using format with names	87
Format columns	87
Examples using format - alignment	88
Format - string	88
Format characters and types	89
Format floating point number	89
f-strings (formatted string literals)	90
printf using old %-syntax	90
Format braces, bracket, and parentheses	91
Examples using format with attributes of objects	91
raw f-strings	91
Lists	93
Anything can be a lists	93
Any layout	93
Lists	94
List slice with steps	95
Change a List	95
Change with steps	96
List assignment and list copy	96

CONTENTS

join	97
join list of numbers	97
split	97
for loop on lists	98
in list	98
Where is the element in the list	99
Index improved	99
[.	99
[.	100
[.	100
Remove element by index [.	101
Remove first element of list	101
Remove several elements of list by index	102
Use list as a queue	102
Queue using deque from collections	102
Fixed size queue	103
List as a stack	104
stack with deque	104
Exercies: Queue	105
Exercise: Stack	106
Solution: Queue with list	106
Solution: Queue with deque	107
Solution: Reverse Polish calculator (stack) with lists	108
Solution: Reverse Polish calculator (stack) with deque	109
Debugging Queue	110
sort	110
sort numbers	111
sort mixed	111
key sort	112
Sort tuples	112
sort with sorted	113
sort vs. sorted	114
key sort with sorted	114
Sorting characters of a string	114
range	114
Looping over index	115
Enumerate lists	115
List operators	116
List of lists	116
List assignment	117
List documentation	117
tuple	117
Exercise: color selector menu	118

CONTENTS

Exercise: count digits	118
Exercise: Create list	119
Exercise: Count words	119
Exercise: Check if number is prime	120
Exercise: DNA sequencing	120
Solution: menu	120
Solution: count digits	121
Solution: Create list	122
Solution: Count words	122
Solution: Check if number is prime	123
Solution: DNA sequencing	123
Solution: DNA sequencing with filter	124
Solution: DNA sequencing with filter and lambda	124
[.	124
append vs. extend	125
split and extend	125
Files	127
Open and read file	127
Filename on the command line	127
Filehandle with and without	127
Filehandle with return	128
Read file remove newlines	128
Read all the lines into a list	129
Read all the characters into a string (slurp)	129
Not existing file	129
Open file exception handling	130
Open many files - exception handling	130
Writing to file	131
Append to file	131
Binary mode	131
Does file exist? Is it a file?	132
Exercise: count numbers	132
Exercise: strip newlines	133
Exercise: color selector	133
Exercise: ROT13	133
Exercise: Combine lists	134
Solution: count numbers	134
Solution: strip newlines	135
Solution: color selector	135
Solution: Combine lists	135
Read text file	136
Open and read file	137

CONTENTS

Direct access of a line in a file	137
Example	138
Dictionary (hash)	140
What is a dictionary	140
When to use dictionaries	140
Dictionary	140
keys	140
Loop over keys	141
Loop using items	141
values	142
Not existing key	143
Get key	143
Does the key exist?	144
Does the value exist?	144
Delete key	145
List of dictionaries	145
Shared dictionary	146
immutable collection: tuple as dictionary key	147
immutable numbers: numbers as dictionary key	148
Sort dictionary by value	148
Sort dictionary keys by value	149
Insertion Order is kept	150
Change order of keys in dictionary - OrderedDict	151
Set order of keys in dictionary - OrderedDict	151
Exercise: count characters	152
Exercise: count words	152
Exercise: count words from a file	153
Exercise: Apache log	154
Exercise: Combine lists again	154
Exercise: counting DNA bases	155
Exercise: Count Amino Acids	155
Exercise: List of dictionaries	155
Exercise: Dictinoary of dictionaries	156
Solution: count characters	156
Solution: count characters with default dict	158
Solution: count words	158
Solution: count words in file	159
Solution: Apache log	160
Solution: Combine lists again	161
Solution: counting DNA bases	161
Solution: Count Amino Acids	162
Loop over dictionary keys	163

CONTENTS

Do not change dictionary in loop	163
Default Dict	164
Sets	166
sets	166
set operations	166
set intersection	166
set subset	167
set symmetric difference	167
set union	168
set relative complement	168
set examples	169
defining an empty set	169
Adding an element to a set (add)	169
Merging one set into another set (update)	170
Functions (subroutines)	171
Defining simple function	171
Defining a function	171
Parameters can be named	172
Mixing positional and named parameters	172
Default values	173
Several defaults, using names	174
Arbitrary number of arguments *	174
Fixed parameters before the others	175
Arbitrary key-value pairs in parameters **	176
Extra key-value pairs in parameters	176
Every parameter option	177
Duplicate declaration of functions (multiple signatures)	177
Recursive factorial	177
Recursive Fibonacci	178
Non-recursive Fibonacci	178
Unbound recursion	179
Variable assignment and change - Immutable	180
Variable assignment and change - Mutable	180
Parameter passing of functions	181
Passing references	181
Function documentation	181
Sum ARGV	182
Copy-paste code	182
Copy-paste code fixed	183
Copy-paste code further improvement	184
Palindrome	184

CONTENTS

Exercise: statistics	185
Exercise: recursive	185
Exercise: Tower of Hanoi	186
Exercise: Merge and Bubble sort	186
Solution: statistics	186
Solution: recursive	187
Solution: Tower of Hanoi	188
Solution: Merge and Bubble sort	189
Modules	191
Before modules	191
Create modules	191
path to load modules from - The module search path	192
sys.path - the module search path	192
Flat project directory structure	192
Absolute path	193
Relative path	193
Python modules are compiled	194
How “import” and “from” work?	194
Runtime loading of modules	194
Conditional loading of modules	195
Duplicate importing of functions	195
Script or library	196
Script or library - import	196
Script or library - from import	197
assert to verify values	197
mycalc as a self testing module	198
doctest	199
Scope of import	200
Export import	201
Export import with all	202
import module	203
Execute at import time	203
Import multiple times	203
Exercise: Number guessing	204
Exercies: Scripts and modules	204
Exercise: Module my_sum	204
Exercise: Convert your script to module	205
Exercise: Add doctests to your own code	205
Solution: Module my_sum	205
Regular Expressions	207
What are Regular Expressions (aka. Regexes)?	207

CONTENTS

What are Regular Expressions good for?	207
Examples	207
Where can I use it ?	208
grep	208
Regexes first match	209
Match numbers	209
Capture	210
Capture more	210
Capture even more	211
findall	211
findall with capture	212
findall with capture more than one	212
Any Character	213
Match dot	214
Character classes	214
Common characer classes	215
Negated character class	215
Optional character	215
Regex 0 or more quantifier	216
Quantifiers	216
Quantifiers limit	216
Quantifiers on character classes	217
Greedy quantifiers	218
Minimal quantifiers	218
Anchors	219
Anchors on both end	220
Match ISBN numbers	221
Matching a section	222
Matching a section - minimal	222
Matching a section negated character class	222
DOTALL S (single line)	222
MULTILINE M	223
Two regex with logical or	224
Alternatives	225
Grouping and Alternatives	225
Internal variables	225
More internal variables	226
Regex DNA	226
Regex IGNORECASE	227
Regex VERBOSE X	227
Substitution	228
findall capture	229
Fixing dates	229

CONTENTS

Duplicate numbers	230
Remove spaces	231
Replace string in assembly code	231
Full example of previous	234
Split with regex	235
Exercises: Regexes part 1	235
Exercise: Regexes part 2	236
Exercise: Sort SNMP numbers	237
Exercise: parse hours log file and give report	238
Exercise: Parse ini file	239
Exercise: Replace Python	240
Exercise: Extract phone numbers	240
Solution: Sort SNMP numbers	241
Solution: parse hours log file and give report	242
Solution: Processing INI file manually	244
Solution: Processing config file	245
Solution: Extract phone numbers	246
Regular Expressions Cheat sheet	246
Fix bad JSON	247
Fix very bad JSON	248
Raw string or escape	249
Remove spaces regex	250
Regex Unicode	250
Anchors Other example	251
Python standard modules	253
Some Standard modules	253
sys	253
Writing to standard error (stderr)	254
Current directory (getcwd, pwd, chdir)	255
OS dir (mkdir, makedirs, remove, rmdir)	255
python which OS are we running on (os, platform)	255
Get process ID	256
OS path	256
Traverse directory tree - list directories recursively	256
os.path.join	257
Directory listing	257
expanduser - handle tilde ~	257
Listing specific files using glob	258
External command with system	258
subprocess	258
subprocess in the background	259
Accessing the system environment variables from Python	260

CONTENTS

Set env and run command	261
shutil	261
time	262
sleep in Python	262
timer	263
Current date and time datetime now	264
Converting string to datetime	264
datetime arithmetics	265
Rounding datetime object to nearest second	265
Signals and Python	265
Sending Signal	265
Catching Signal	266
Catching Ctrl-C on Unix	266
Catching Ctrl-C on Unix confirm	267
Alarm signal and timeouts	267
deep copy list	268
deep copy dictionary	270
Exercise: Catching Ctrl-C on Unix 2nd time	271
Exercise: Signals	272
Ctrl-z	272
JSON	273
JSON - JavaScript Object Notation	273
dumps	273
loads	274
dump	274
load	275
Round trip	275
Pretty print JSON	276
Sort keys in JSON	277
Set order of keys in JSON - OrderedDict	278
Exercise: Counter in JSON	279
Exercise: Phone book	279
Exercise: Processes	280
Solution: Counter in JSON	280
Solution: Phone book	281
Command line arguments with argparse	283
Modules to handle the command line	283
argparse	283
Basic usage of argparse	284
Positional argument	285
Many positional argument	286

CONTENTS

Convert to integers	286
Convert to integer	287
Named arguments	287
Boolean Flags	288
Short names	289
Exercise: Command line parameters	289
Exercise: argparse positional and named	289
Exception handling	290
Hierarchy of calls	290
Handling errors as return values	290
Handling errors as exceptions	291
A simple exception	291
Working on a list	292
Catch ZeroDivisionError exception	293
Module to open files and calculate something	294
File for exception handling example	294
Open files - exception	295
Handle divide by zero exception	296
Handle files - exception	296
Catch all the exceptions and show their type	297
List exception types	298
Exceptions	299
How to raise an exception	299
Stack trace	300
Exercies: Exception int conversion	301
Exercies: Raise Exception	302
Solution: Exception int conversion (specific)	302
Solution: Exception int conversion (all other)	303
Solution: Raise Exception	304
Classes - OOP - Object Oriented Programming	305
Why Object Oriented Programming?	305
Generic Object Oriented Programming terms	305
OOP in Python	305
OOP in Python (numbers, strings, lists)	305
OOP in Python (argparse)	306
Create a class	306
Import module containing class	307
Import class from module	307
Initialize a class - constructor, attributes	308
Attributes are not special	308
Create Point class	309

CONTENTS

Initialize a class - constructor, attributes	309
Methods	309
Stringify class	310
Inheritance	311
Inheritance - another level	312
Modes of method inheritance	313
Modes of method inheritance - implicit	313
Modes of method inheritance - override	313
Modes of method inheritance - extend	314
Modes of method inheritance - delegate - provide	315
Composition - Line	315
Some comments	316
Class in function	316
Serialization of instances with pickle	316
Quick Class definition and usage	317
Exercise: Add move_rad to based on radians	317
Exercise: Improve previous examples	318
Exercise: Polygon	318
Exercise: Number	319
Exercise: Library	319
Exercise: Bookexchange	319
Exercise: Represent turtle graphics	319
Solution - Polygon	319
PyPi - Python Package Index	321
What is PyPi?	321
Easy Install	321
pip	321
Upgrade pip	321
PYTHONPATH	321
Virtualenv	321
Virtualenv for Python 3	322
SQLite Database Access	323
SQLite	323
Connecting to SQLite database	323
Create TABLE in SQLite	323
INSERT data into SQLite database	324
SELECT data from SQLite database	325
A counter	325
MySQL	328
Install MySQL support	328
Create database user (manually)	328

CONTENTS

Create database (manually)	328
Create table (manually)	329
Connect to MySQL	329
Connect to MySQL and Handle exception	330
Select data	330
Select more data	331
Select all data fetchall	332
Select some data fetchmany	332
Select some data WHERE clause	333
Select into dictionaries	334
Insert data	335
Update data	335
Delete data	336
Exercise MySQL	337
Exercise: MySQL Connection	337
Solution: MySQL Connection	337
PostgreSQL	339
PostgreSQL install	339
Python and Postgresql	339
PostgreSQL connect	339
INSERT	339
INSERT (from command line)	340
SELECT	341
DELETE	341
SQLAlchemy	343
SQLAlchemy hierarchy	343
SQLAlchemy engine	343
SQLAlchemy autocommit	343
SQLAlchemy engine CREATE TABLE	343
SQLAlchemy engine INSERT	344
SQLAlchemy engine SELECT	344
SQLAlchemy engine SELECT all	345
SQLAlchemy engine SELECT fetchall	345
SQLAlchemy engine SELECT aggregate	346
SQLAlchemy engine SELECT IN	346
SQLAlchemy engine SELECT IN with placeholders	347
SQLAlchemy engine connection	347
SQLAlchemy engine transaction	347
SQLAlchemy engine using context managers	349
Exercise: Create table	349
SQLAlchemy Metada	349

CONTENTS

SQLAlchemy types	351
SQLAlchemy ORM - Object Relational Mapping	352
SQLAlchemy ORM create	352
SQLAlchemy ORM schema	353
SQLAlchemy ORM reflection	354
SQLAlchemy ORM INSERT after automap	354
SQLAlchemy ORM INSERT	355
SQLAlchemy ORM SELECT	355
SQLAlchemy ORM SELECT cross tables	356
SQLAlchemy ORM SELECT and INSERT	356
SQLAlchemy ORM UPDATE	357
SQLAlchemy ORM logging	358
Solution: Create table	358
Exercise: Inspector	359
SQLAlchemy CREATE and DROP	360
SQLAlchemy Notes	361
SQLAlchemy Meta SQLite CREATE	361
SQLAlchemy Meta Reflection	362
SQLAlchemy Meta INSERT	362
SQLAlchemy Meta SELECT	362
NoSQL	363
Types of NoSQL databases	363
MongoDB	364
MongoDB CRUD	364
Install MongoDB support	364
Python MongoDB insert	364
MongoDB CLI	365
Python MongoDB find	365
Python MongoDB find refine	366
Python MongoDB update	366
Python MongoDB remove (delete)	366
Redis	368
Redis CLI	368
Redis list keys	368
Redis set get	368
Redis incr	369
Redis incrby	369
Redis setex	369
Web client	371
urllib the web client	371

CONTENTS

urllib2 the web client	371
httpbin.org	372
requests get	372
Download image using requests	372
Download image as a stream using requests	372
Download zip file	373
Extract zip file	373
Interactive Requests	373
requests get JSON	374
requests get JSON UserAgent	374
requests get JSON UserAgent	374
requests get header	375
requests change header	375
requests post	376
Tweet	376
API config file	377
bit.ly	377
Exercise: Combine web server and client	378
Python Web server	379
Hello world web	379
Dump web environment info	379
Web echo	380
Web form	381
Resources	382
Python Flask	383
Python Flask intro	383
Python Flask installation	383
Flask: Hello World	383
Flask hello world + test	383
Flask generated page - time	384
Flask: Echo GET	385
Flask: Echo POST	387
Flask: templates	388
Flask: templates	389
Flask: templates with parameters	389
Flask: runner	390
Exercise: Flask calculator	391
Static files	391
Flask Logging	392
Flask: Counter	392
Color selector without session	393

CONTENTS

Session management	394
Flask custom 404 page	394
Flask Error page	395
Flask URL routing	396
Flask Path params	396
Flask Path params (int)	397
Flask Path params add (int)	397
Flask Path params add (path)	398
Jinja loop, conditional, include	398
Exercise: Flask persistent	400
Exercise: Flask persistent	400
Flask Exercises	400
Flask login	401
Flask JSON API	402
Flask and AJAX	403
Flask and AJAX	406
passlib	408
Flask Testing	408
Flask Deploy app	410
Flask Simple Authentication + test	411
Flask REST API	412
Flask REST API - Echo	412
Flask REST API - parameters in path	413
Flask REST API - parameter parsing	414
Flask REST API - parameter parsing - required	415
Networking	417
Secure shell	417
ssh	417
ssh from Windows	417
Parallel ssh	418
telnet	418
prompt for password	419
Python nmap	419
ftp	420
Interactive shell	422
The Python interactive shell	422
REPL - Read Evaluate Print Loop	422
Using Modules	423
Getting help	424
Exercise: Interactive shell	425
Testing Demo	426

CONTENTS

How do you test your code?	426
What is testing?	426
What is testing really?	426
Testing demo - AUT - Application Under Test	426
Testing demo - use the module	426
Testing demo: doctets	427
Testing demo: Unittest success	428
Testing demo: Unittest failure	428
Testing demo: pytest using classes	429
Testing demo: pytest without classes	430
Testing demo: pytest run doctests	431
Testing demo: pytest run unittest	431
Exercise: Testing demo	432
Solution: Testing demo	432
Types in Python	434
mypy	434
Types of variables	434
Types of function parameters	434
Types used properly	435
TODO: mypy	435
Testing Intro	436
The software testing equasion	436
The software testing equasion (fixed)	436
The pieces of your software?	436
Manual testing	436
What to tests?	436
Continuous Integration	437
Functional programming	438
Functional programming	438
Iterators (Iterables)	438
range	439
range with list	441
range vs. list size	442
for loop with transformation	443
map	444
map delaying function call	446
map on many values	447
map with list	448
double with lambda	449
What is lambda in Python?	450
lambda returning tuple	451

CONTENTS

map returning tuples	451
lambda with two parameters	452
map for more than one iterable	452
map on uneven lists	452
replace None (for Python 2)	453
map on uneven lists - fixed (for Python 2)	453
map mixed iterators	454
map fetch value from dict	454
Exercise: string to length	455
Exercise: row to length	455
Exercise: compare rows	455
Solution: string to length	455
Solution: row to length	455
Solution: compare rows	456
filter	456
filter with lambda	457
filter - map example	457
filter - map in one expression	458
Get indexes of values	459
reduce	460
reduce with default	461
zip	462
Creating dictionary from two lists using zip	462
all, any	463
Compare elements of list with scalar	463
List comprehension - double	464
List comprehension - simple expression	464
List generator	465
List comprehension	466
Dict comprehension	467
Lookup table with lambda	467
Read lines without newlines	467
Read key-value pairs	468
Create index-to-value mapping in a dictionary based on a list of values	468
Exercise: min, max, factorial	469
Exercise: Prime numbers	469
Exercise: Many validator functions	469
Exercise: Calculator using lookup table	470
Exercise: parse file	470
Solution: min, max, factorial	471
Solution: Prime numbers	472
Solution: Many validator functions	472
Solution: Calculator using lookup table	472

CONTENTS

map with condtion	473
map with lambda	473
map with lambda with condition	474
List comprehension - complex	474
Iterators - with and without Itertools	475
Advantages of iterators and generators	475
The Fibonacci research institute	475
Fibonacci plain	475
Fibonacci copy-paste	475
Iterators Glossary	476
What are iterators and iterables?	476
A file-handle is an iterator	478
range is iterable but it is not an iterator	478
Iterator: a counter	480
Using iterator	480
Iterator without temporary variable	481
The type of the iterator	481
Using iterator with next	482
Mixing for and next	482
Iterable which is not an iterator	483
Iterator returning multiple values	484
Range-like iterator	484
Unbound or infinite iterator	485
Unbound iterator Fibonacci	486
Operations on Unbound iterator	488
itertools	488
itertools - count	489
itertools - cycle	489
Exercise: iterators - reimplement the range function	490
Exercise: iterators - cycle	490
Exercise: iterators - alter	490
Exercise: iterators - limit Fibonacci	491
Exercise: iterators - Fibonacci less memory	491
Exercise: read char	491
Exercise: read section	491
Exercise: collect packets	492
Exercise: compare files	493
Solution: iterators - limit Fibonacci	494
Solution: iterators - Fibonacci less memory	495
Solution: read section	495
Solution: compare files	496
Solution: collect packets	497

CONTENTS

Generators and Generator Expressions	500
Generators Glossary	500
Iterators vs Generators	500
List comprehension and Generator Expression	500
List comprehension vs Generator Expression - less memory	501
List comprehension vs Generator Expression - lazy evaluation	503
Generator: function with yield - call next	504
Generators - call next	505
Generator with yield	505
Generators - fixed counter	506
Generators - counter	506
Generators - counter with parameter	507
Generators - my_range	508
Fibonacci - generator	509
Infinite series	509
Integers	509
Integers + 3	510
Integers + Integers	510
Filtered Fibonacci	511
The series.py	512
generator - unbound count (with yield)	513
iterator - cycle	513
Exercise: Alternator	514
Exercise: Prime number generator	514
Exercise: generator	514
Exercise: Tower of Hanoi	515
Exercise: Binary file reader	515
Exercise: File reader with records	515
Logging	517
Simple logging	517
Simple logging - set level	517
Simple logging to a file	518
Simple logging format	518
Simple logging change date format	518
getLogger	519
Time-based logrotation	520
Size-based logrotation	520
Closures	522
Counter local - not working	522
Counter with global	522
Create incrementors	523

CONTENTS

Create internal function	523
Create function by a function	524
Create function with parameters	524
Counter closure	525
Make incrementor with def (closure)	526
Make incrementor with lambda	526
Exercise: closure bank	527
Solution: closure bank	527
Solution: counter with parameter	528
Decorators	530
Function assignment	530
Function inside other function	530
Decorator	531
Use cases for decorators in Python	532
A recursive Fibonacci	532
trace fibo	532
tron decorator	533
Decorate with direct call	533
Decorate with parameter	534
Decorator accepting parameter	534
Decorate function with any signature	535
Decorate function with any signature - implementation	535
Exercise: Logger decorator	536
Exercise: memoize decorator	536
Solution: Logger decorator	536
Solution: Logger decorator (testing)	537
Solution memoize decorator	538
Context managers (with statement)	540
Why use context managers?	540
Context Manager examples	541
cd in a function	541
open in function	543
open in for loop	544
open in function using with	544
Plain context manager	545
Param context manager	545
Context manager that returns a value	546
Use my tempdir - return	547
Use my tempdir - exception	548
cwd context manager	548
tempdir context manager	549

CONTENTS

Context manager with class	550
Context managers with class	551
Context manager: with for file	552
With - context managers	553
Exercise: Context manager	553
Exercise: Tempdir on Windows	554
Solution: Context manager	554
Advanced lists	556
Change list while looping: endless list	556
Change list while looping	556
Copy list before iteration	556
for with flag	557
for else	557
enumerate	558
do while	558
list slice is copy	559
Advanced Exception handling	560
Exceptions else	560
Exceptions finally	561
Exit and finally	562
Catching exceptions	562
Home made exception	563
Home made exception with attributes	564
Home made exception hierarchy	565
Home made exception hierarchy - 1	565
Home made exception hierarchy - 2	566
Home made exception hierarchy - 3	566
Exercise: spacefight with exceptions	568
Exercies: Raise My Exception	569
Solution: spacefight with exceptions	569
Solution: Raise My Exception	572
Exception finally return	573
Warnings	574
Warnings	574
CSV	575
Reading CSV the naive way	575
CSV with quotes and newlines	575
Reading a CSV file	576
CSV dialects	576
CSV to dictionary	577

CONTENTS

Exercise: CSV	578
Solution: CSV	578
Excel	580
Spreadsheets	580
Python Excel	580
Create an Excel file from scratch	580
Worksheets in Excel	581
Add expressions to Excel	581
Format field	581
Number series and chart	582
Read Excel file	583
Update Excel file	583
Exercise: Excel	584
XML	585
XML Data	585
Expat - Callbacks	585
XML DOM - Document Object Model	586
XML SAX - Simple API for XML	587
SAX collect	588
XML elementtree	589
SciPy - for Scientific Computing in Python	591
Data Science tools in Python	591
Data Analysis resources	591
Python and Biology	593
Biopython	593
Biopython background	593
Bio python sequences	593
Download data	594
Read FASTA, GenBank files	594
Search nucleotids	595
Download nucleotids	595
Exercise: Nucleotid	596
Biology background	597
Chemistry	598
Chemistry links	598
Bond length	598
Covalent radius	599
Python energy landscape explorer	599
Other chemistry links	599

CONTENTS

numpy	600
What is NumPy	600
NumPy - vector	600
NumPy 2D arrays	600
NumPy - set type	601
NumPy arrays: ones and zeros	601
NumPy: eye	602
NumPy array random	603
NumPy Random integers	603
NumPy array type change by division (int to float)	604
NumPy: Array methods: transpose	604
NumPy: reference, not copy	605
NumPy: copy array	606
NumPy: Elementwise Operations on Arrays	606
NumPy: multiply, matmul, dot for vectors	607
NumPy: multiply, matmul, dot for vector and matrix	607
NumPy: multiply, matmul, dot for matrices	608
NumPy: casting - converting from strings to integer.	609
NumPy: indexing 1d array	610
NumPy: slice is a reference	610
NumPy: slice - copy	611
NumPy: abs value on a Numpy array	611
NumPy: Logical not on a Numpy array	612
NumPy: Vectorize a function	613
NumPy: Vectorize len	614
NumPy: Vectorize lambda	614
NumPy: Filtering array	614
NumPy: Filter matrix values	615
NumPy: Filter matrix rows	616
NumPy: Stat	617
NumPy: Serialization	617
NumPy: Load from Matlab file	618
NumPy: Save as Matlab file	618
NumPy: Horizontal stack vectors (hstack)	618
NumPy: Append or vertically stack vectors and matrices (vstack)	619
NumPy uint8	619
NumPy int8	620
Pandas	621
Pandas	621
Planets	621
Pandas Planets - Dataframes	621
Pandas Stocks	622

CONTENTS

Pandas Stocks	623
Merge Dataframes	623
Analyze Alerts	625
Analyze IFMetrics	625
Create Excel file for experiment with random data	625
Calculate Genome metrics	626
Calculate Genome metrics - add columns	627
Calculate Genome metrics - vectorized	628
Calculate Genome metrics - vectorized numpy	628
Genes using Jupyter	629
Combine columns	629
Pandas more	630
Pandas Series	631
Pandas Series with names	632
Matplotlib	634
About Matplotlib	634
Matplotlib Line	634
Matplotlib Line with dates	635
Matplotlib Simple Pie	636
Matplotlib Simple Pie with params	637
Matplotlib Pie	638
Matplotlib Pie 2	639
Plot, scatter, histogram	640
Seaborn	641
Seaborn use examples	641
Seaborn tip	641
Seaborn Anscombes Quartet	642
Jupyter notebooks	644
Jupyter on Windows	644
Jupyter on Linux and OSX	644
Jupyter add	644
Planets	645
Jupyter notebook Planets	645
Jupyter StackOverflow	646
Jupyter StackOverflow - selected columns	647
Jupyter processing chunks	647
Jupyter StackOverflow - selected rows	647
Jupyter StackOverflow - biggest countries (in terms of number of responses)	648
Jupyter StackOverflow - histogram	649
Jupyter StackOverflow - filter by country	649
Jupyter StackOverflow - OpenSourcer	649

CONTENTS

Jupyter StackOverflow - cross tabulation	649
Jupyter StackOverflow - salaries	650
Jupyter StackOverflow - replace values	650
Jupyter StackOverflow - selected rows	650
Jupyter notebook Intellisense (TAB completion)	651
Jupyter examples	651
IPy Widgets	651
Testing	652
Traditional Organizations	652
Quality Assurance	652
Web age Organizations	652
TDD vs Testing as an Afterthought	652
Why test?	653
Testing Modes	653
Testing Applications	653
Testing What to test?	653
Testing in Python	654
Testing Environment	654
Testing Setup - Fixture	654
Testing Resources	654
Testing with unittest	655
Use a module	655
Test a module	655
The tested module	656
Testing - skeleton	656
Testing	657
Test examples	658
Testing with PyTest	659
Pytest features	659
Pytest setup	659
Testing with Pytest	659
Testing functions	660
Testing class and methods	660
Pytest - execute	661
Pytest - execute	661
Pytest simple module to be tested	661
Pytest simple tests - success	661
Pytest simple tests - success output	662
Pytest simple tests - failure	662
Pytest simple tests - failure output	662
Exercise: test math functions	663

CONTENTS

Exercise: test this app	663
Exercise: test the csv module	664
Solution: Pytest test math functions	664
Solution: Pytest test this app	665
Solution: test the csv module	665
PyTest bank deposit	666
PyTest expected exceptions (bank deposit)	666
PyTest expected exceptions (bank deposit) - no exception happens	667
PyTest expected exceptions (bank deposit) - different exception is raised	668
PyTest expected exceptions	668
PyTest expected exceptions output	668
PyTest expected exceptions (text changed)	669
PyTest expected exceptions (text changed) output	669
PyTest expected exceptions (other exception)	669
PyTest expected exceptions (other exception) output	670
PyTest expected exceptions (no exception)	670
PyTest expected exceptions (no exception) output	671
PyTest: Multiple Failures	671
PyTest: Multiple Failures output	672
PyTest Selective running of test functions	672
PyTest: stop on first failure	672
Pytest: expect a test to fail (xfail or TODO tests)	672
Pytest: expect a test to fail (xfail or TODO tests)	673
PyTest: show xfailed tests with -rx	673
Pytest: skipping tests	674
Pytest: show skipped tests with -rs	675
Pytest: show extra test summary info with -r	675
Pytest: skipping tests output in verbose mode	675
Pytest verbose mode	676
Pytest quiet mode	676
PyTest print STDOUT and STDERR using -s	677
PyTest failure reports	677
PyTest compare numbers	677
PyTest compare numbers relatively	677
PyTest compare strings	678
PyTest compare long strings	678
PyTest is one string in another strings	679
PyTest test any expression	680
PyTest element in list	680
PyTest compare lists	680
PyTest compare short lists	681
PyTest compare short lists - verbose output	681
PyTest compare dictionaries	682

CONTENTS

PyTest compare dictionaries output	682
PyTest Fixtures	683
PyTest Fixture setup and teardown	683
PyTest Fixture setup and teardown output	684
PyTest: Class setup and teardown	685
PyTest: Class setup and teardown output	686
Pytest Dependency injection	686
Pytest fixture - tmpdir	687
Pytest capture STDOUT and STDERR with capsys	687
Pytest Fixture - home made fixtures	688
More fixtures	689
Pytest: Mocking - why?	691
Pytest: Mocking - what?	691
Pytest: One dimensional spaceflight	691
Pytest: Mocking input and output	693
Pytest: Mocking random	693
Pytest: Flask echo	694
Pytest: testing Flask echo	695
PyTest: Run tests in parallel with xdist	696
PyTest: Order of tests	696
PyTest: Randomize Order of tests	696
PyTest: Force default order	696
PyTest: no random order	697
Anagram on the command line	697
PyTest testing CLI	697
PyTest test discovery	698
PyTest test discovery - ignore some tests	699
PyTest select tests by name	700
PyTest select tests by marker	701
PyTest: Test Coverage	702
Exercise: module	702
Exercise: Open Source	703
Pytest resources	703
Pytest and tempdir	703
PyTest compare short lists - output	704
PyTest with parameter	705
PyTest with parameters	706
Pytest reporting in JUnit XML format	706
No test selected	707
Advanced functions	708
Variable scopes	708
Name resolution order (LEGB)	708

CONTENTS

Scoping: global seen from fuction	708
Assignment creates local scope	708
Local scope gone wrong	709
Changing global variable from a function	710
Global variables mutable in functions	710
Scoping issues	710
sub in sub	711
Scoping sub in sub (enclosing scope)	711
Function objects	712
Functions are created at run time	712
Mutable default	713
Use None as default parameter	713
Inner function created every time the outer function runs	714
Static variable	715
Static variable in generated function	715
Inspect	716
Variable number of function arguments	718
Python function arguments - a reminder	718
Functions with unknown number of argumerns	718
Variable length argument list with * and **	719
Passing arguments as they were received (but incorrectly)	719
Unpacking args before passing them on	720
Exercise: implement the my_sum function	720
Solution: implement the my_sum function	721
Exercise: implement the reduce function	721
Soluton: implement the reduce function	721
Exercise: sort pairs	722
Solution: sort pairs	722
Python Packages	724
Why Create package	724
Create package	724
Internal usage	724
use module in package - relative path	725
use package (does not work)	725
package importing (and exporting) module	726
use package (module) with import	726
use package with import	726
Creating an installable Python package	727
Create tar.gz file	727
Install Package	728
Dependencies	729

CONTENTS

Add README file	729
Add README file (setup.py)	730
Include executables	730
Add tests	731
Add tests calc	732
Add tests all	732
setup.py	733
Run tests and create package	733
Packaging applications (creating executable binaries)	733
Using PyInstaller	734
Other PyInstaller examples	734
Other	734
Py2app for Mac	734
Exercise: package	735
Exercise: create executable	735
Ctypes	736
ctypes - hello	736
concat	737
links	738
Advanced OOP	739
Class count instances	739
Class Attributes	739
Class Attributes in Instances	740
Attributes with method access	741
Instance Attribute	741
Methods are class attributes	742
Monkey patching	743
Classes: instance method	744
Class methods and class attributes	745
Classes: constructor	746
Class methods - alternative constructor	747
Abstract Base Class	748
Abstract Base Class with abc	749
ABC working example	749
ABC - cannot instantiate the base-class	750
ABC - must implement methods	750
Use Python @property to fix bad interface (the bad interface)	751
Use Python @property to fix bad interface (first attempt)	751
Use Python @property to fix bad API	752
Use Python @property decorator to fix bad API	753
Use Python @property for value validation	754

CONTENTS

class and static methods	755
Destructor: del	757
Destructor delayed	758
Destructor delayed for both	758
Opearator overloading	759
Operator overloading methods	760
Exercise: rectangular	760
Exercise: SNMP numbers	761
Exercise: Implement a Gene inheritance model combining DNA	761
Exercise: imaginary numbers - complex numbers	761
Solution: Rectangular	762
Solution: Implement a Gene inheritance model combining DNA	765
Instance counter	766
2to3	767
Convertig from Python 2 to Python 3	767
division	767
print in Python 2	767
print in Python 3	767
input and raw_input	768
Code that works on both 2 and 3	768
Compare different types	768
Octal numbers	769
2to3 Resources	769
Design Patterns	770
What are Design Patterns?	770
Don't replace built-in objects	770
Facade - simple interface to complex system	770
Monkey Patching	771
Creation DPs "Just One"	772
Singleton	772
Monostate (Borg)	773
Dispatch table	773
Parallel	774
Types of Problems	774
Types of solutions	774
How many parallels to use?	774
Dividing jobs	774
Performance Monitoring	775
Threads	776
Python Threading docs	776

CONTENTS

Threaded counters	776
Simple threaded counters	777
Simple threaded counters (parameterized)	779
Pass parameters to threads - Counter with attributes	780
Create a central counter	782
Lock - acquire - release	782
Counter - plain	783
GIL - Global Interpreter Lock	784
Thread load	785
Exercise: thread files	786
Exercise: thread URL requests.	786
Exercise: thread queue	789
Solution: thread queue	790
Solution: thread URL requests.	791
Forking	793
Fork	793
Forking	793
Fork skeleton	794
Fork with load	795
Fork load results	796
Marshalling / Serialization	797
Fork with random	798
Exercise: fork return data	798
Solution: fork return data	799
Asynchronous programming with AsyncIO	801
Sync chores	801
Async chores	803
Explanation	805
Coroutines	806
More about asyncio	806
Async files	806
Asynchronous programming with Twisted	807
About Twisted	807
Echo	807
Echo with log	808
Simple web client	809
Web client	810
Multiprocess	813
Multiprocess CPU count	813
Multiprocess Process	813

CONTENTS

Multiprocess N files: Pool	813
Multiprocess load	814
Multiprocess: Pool	815
Multiprocess load async	816
Multiprocess and logging	817
Exercise: Process N files in parallel	818
Exercise: Process N Excel files in parallel	818
Exercise: Fetch URLs in parallel	819
Exercise: Fetch URLs from one site.	821
Solution: Fetch URLs in parallel	822
Multitasking	825
What is Multitasking?	825
Multitasking example	825
Multitasking example with wait	826
Multitasking - second loop waits for first one	827
Multitasking counter	828
Multitasking counter with thread locking	829
Improving Performance - Optimizing code	830
Problems	830
Optimization strategy	830
Locate the source of the problem	830
Optimizing tactics	830
DSU: Decorate Sort Undecorate	831
Profile code	831
Slow example	831
profile slow code	833
cProfile slow code	833
Benchmarking	834
Benchmarking subs	835
Levenshtein distance	835
Generate words	836
Levenshtein - pylev	836
Levenshtein - editdistance	837
Editdistance benchmark	837
A Tool to Generate text files	837
Count characters	839
Memory leak	840
Garbage collection	841
Weak reference	842
Exercise: benchmark list-comprehension, map, for	843
Exercise: Benchmark Levenshtein	843

CONTENTS

Exercise: sort files	843
Exercise: compare split words:	843
Exercise: count words	844
GUI with Python/Tk	846
Sample Tk app	846
GUI Toolkits	850
Installation	850
Python Tk Documentation	851
Python Tk Button	851
Python Tk Button with action	852
Python Tk Label	852
Python Tk Label - font size and color	853
Python Tk Keybinding	853
Python Tk Entry (one-line text entry)	854
Python Tk Entry for passwords and other secrets (hidden text)	855
Python Tk Checkbox	855
Python Tk Radiobutton	856
Python Tk Listbox	857
Python Tk Listbox Multiple	857
Python Tk Menubar	858
Python Tk Text	860
Python Tk Dialogs	860
Python Tk Filedialog	860
Python Tk messagebox	862
Python Tk Combobox	863
Python Tk OptionMenu	864
Python Tk Scale	865
Python Tk Progressbar	866
Python Tk Frame	866
Not so Simple Tk app with class	868
Tk: Hello World	868
Tk: Quit button	869
Tk: File selector	870
Tk: Checkbox	871
Tk: Runner	872
Tk: Runner with threads	874
Getting started with Tk	878
Exercise: Tk - Calculator one line	879
Exercise: Tk Shopping list	879
Exercise: Tk TODO list	880
Exercise: Tk Notepad	880
Exercise: Tk Copy files	880

CONTENTS

Exercise: Tk	880
Solution: Tk - Calculator one line	880
Solution: Tk	883
Solution: Tk Notepad	884
Simple file dialog	886
Python Pitfalls	887
Reuse of existing module name	887
Use the same name more than once	887
Compare string and number	888
Compare different types	889
Sort mixed data	889
Linters	891
Static Code Analyzis - Linters	891
PEP8	891
F811 - redefinition of unused	891
Warn when Redefining functions	891
Python .NET	893
IronPython	893
Use .NET libraries from Python	893
Python and .NET console	894
Python and .NET examples	894
Exercise Python and .NET	896
Python and Java	897
Jython	897
Calling Java from Python	897
Jython - Python running on the JVM	898
Jython Installation	898
Jython Installation	898
Jython load Java class	898
Jython load Java class in code	898
Jython test Java class	899
PIL - Pillow	900
Install Pillow	900
Create First Image	900
Write Text on Image	900
Select font for Text on Image	901
Font directories	901
Get size of an Image	902

CONTENTS

Get size of text	902
Resize an existing Image	902
Crop an existing Image	902
Combine two images	903
Rotated text	903
Rotated text in top-right corner	904
Embed image (put one image on another one)	904
Draw a triangle	905
Draw a triangle and write text in it	905
Draw a triangle and write rotated text in it	906
Draw a rectangular	907
Draw a rectangle	907
Draw circle	907

First steps

What is Python?

- A snake.
- A British comedy group called [Monty Python](https://en.wikipedia.org/wiki/Monty_Python)¹.
- A programming language. The definition of the language: words, punctuation (operators) and grammar (syntax).
- The compiler/interpreter of the Python programming language. (aka. CPython).

When people say they Python in relation to programming they either mean the Python programming language or they mean the tool that can translate some text (code) written in the Python programming language to the language a computer can actually understand. On MS Windows this is the **python.exe** you need to install. On Linux/Mac it is usually called **python** or **python3**. The generic name of the tool that translates a programming language for the computer is either called a compiler or an interpreter. We'll talk about this later on.

What is needed to write a program?

- An **editor** where we can write in a language.
- A **compiler or interpreter** that can translate our text to the language of the computer.

In order to write and run a program you basically need two things. A text editor in which you can write the program and a compiler or interpreter that can translate this program to the computer.

¹https://en.wikipedia.org/wiki/Monty_Python

The source (code) of Python

- [Python²](https://www.python.org/)

Python 2 vs. Python 3

- Python 2.x - old, legacy code at companies, answers on the Internet. Retires on January 1, 2020.
- Python 3.x - the one that you should use. (not fully backward compatible) Available since December 3, 2008.

Python has two major lines the version 2.x and the version 3.x. In a nutshell you **should** always use Python 3 if possible.

Unfortunately you can still encounter many companies and many projects in companies that are stuck on Python 2.

In such cases you probably will have to write in Python 2.

In addition when you search for solutions on the Internet in many cases you'll encounter solution that were written

for Python 2. Luckily in most of the cases it is almost trivial to convert these small examples to work on Python 3.

You just need to be able to recognize that the code was originally written for Python 2 and you need to be able to make the adjustments.

For this reason, while the majority of these pages cover Python 3, we are going to point out the places where it might be useful to know how Python 2 works.

You are free to skip these parts and come back to them when the need arises.

Installation

- MS Windows
- Linux
- Apple/Mac OSX

²<https://www.python.org/>

We are going to cover how to install Python all 3 major operating systems.

Installation on Linux

- On Linux you usually have Python 2 installed in `/usr/bin/python`
- Python 3 in `/usr/bin/python3`.
- If they are not installed, you can install them with the appropriate `yum` or `apt-get` command of your distribution.
- An alternative is to install [Anaconda with Python 3.x](#)³

```
1 $ which python3
2
3 $ sudo apt-get install python3
4 $ sudo yum install python3
```

Installation on Apple Mac OSX

- On Mac OSX you can have Python 2 installed in `/usr/bin/python` and Python 3 installed as `/usr/bin/python3`.
- [Homebrew](#)⁴
- An alternative is to install [Anaconda with Python 3.x](#)⁵

```
1 $ which python3
2
3 $ brew install python3
```

Installation on MS Windows

- [Anaconda with Python 3.x](#)⁶
- Anaconda shell
- Anaconda Jupyter notebook

*

- An alternative is to [install from here](#)⁷.

⁵<https://www.anaconda.com/download/>

⁶<https://www.anaconda.com/download/>

⁷<http://www.python.org/download/>

Editors, IDEs

Basically you can use any text editor to write Python code. The minimum I recommend is to have proper syntax highlighting. IDEs will also provide intellisense, that is, in most of the cases they will be able to understand what kind of objects do you have in your code and will be able to show you the available methods and their parameters. Even better, they provide powerful debuggers.

PyCharm seems to be the most popular IDE. It has a free version called community edition.

Documentation

- [Google](#)³⁴
- [Bing](#)³⁵
- [DuckDuckGo](#)³⁶
- [official documentation of Python](#)³⁷
- [Stack Overflow](#)³⁸
- [Code Maven](#)³⁹
- ...

Program types

- Desktop application (MS Word, MS Excel, calculator, Firefox, Chrome, ...)
- Mobile applications - whatever runs on your phone.
- Embedded applications - software in your car or in your shoelace.
- Web applications - they run on the web server and send you HTML that your browser can show.
- **Command Line Applications**
- Scripts and programs are the same for our purposes
- ...

Python on the command line

More or less the only thing I do on the command line with python is to check the version number:

```
1 python -V
2 python --version
```

You can run some Python code without creating a file, but I don't remember ever needing this. If you insist

```
1 python -c "print 42"
```

³⁴<https://www.google.com/>

³⁵<https://www.bing.com/>

³⁶<https://duckduckgo.com/>

³⁷<https://docs.python.org/>

³⁸<https://stackoverflow.com/>

³⁹<https://code-maven.com/python>

```
1 python3 -c "print(42)"
```

Type the following to get the details:

```
1 man python
```

[cmdline](#)⁴⁰

First script - hello world

```
1 print("Hello World")
```

- Create a file called **hello.py** with the above content.
- Open your terminal or the Anaconda Prompt on MS Windows in the directory (folder)
- Change to the directory where you saved the file.
- Run it by typing **python hello.py** or **python3 hello.py**
- The extension is .py - mostly for the editor (but also for modules).
- Parentheses after print() are required in Python 3, but use them even if you are stuck on Python 2.

Examples

- [The examples are on GitHub](#)⁴¹
- You can download them and unzip them.

Comments

marks single line comments.

There are no real multi-line comments in Python, but we will see a way to have them anyway.

⁴⁰<https://docs.python.org/using/cmdline.html>

⁴¹<https://github.com/szabgab/slides>

```
1 print("hello")
2
3 # Comments for other developers
4
5 print("world") # more comments
6
7 # print("This is not printed")
```

Variables

```
1 greeting = "Hello World!"
2 print(greeting)
```

Exercise: Hello world

Try your environment:

- Make sure you have access to the right version of Python.
- Install Python if needed.
- Check if you have a good editor with syntax highlighting.
- Write a simple script that prints **Hello world**.
- Add some comments to your code.
- Create a variable, assign some text to it and then print out the content of the variable.

What is programming?

- Use some language to tell the computer what to do.
- Like a cooking recipe it has step-by-step instructions.
- Taking a complex problem and dividing it into small steps a computer can do.

What are the programming languages

- A computer CPU is created from transistors, 1 and 0 values. (aka. bits)
- Its language consists of numbers. (e.g 37 means move the content of ax register to bx register)
- English? too complex, too much ambiguity.
- Programming languages are in-between.

A written human language

- Words
- Punctuation: - . , ! ?
- Grammar
- ...

A programming language

- Built-in words: print, len, type, def, ...
- Literal values: numbers, strings⁴²
- Operators: + - * = , ; ...⁴³
- Grammar (syntax)⁴⁴
- User-created words: variables, functions, classes, ...

Words and punctuation matter!

- What did you chose? (Correctly: choose, but people will usually understand.)
- Lets do the homework. (Correctly: Let's, but most people will understand.)
- Let's eat, grandpa!
- Let's eat grandpa!
- [see more](#)⁴⁵
- Programming languages have a lot less words, but they are very strict on the grammar (syntax).
- A missing comma can break your code.
- A missing space will change the meaning of your code.
- An incorrect word can ruin your day.

Literals, Value Types in Python

⁴²[https://en.wikipedia.org/wiki/Literal_\(computer_programming\)](https://en.wikipedia.org/wiki/Literal_(computer_programming))

⁴³[https://en.wikipedia.org/wiki/Operator_\(computer_programming\)](https://en.wikipedia.org/wiki/Operator_(computer_programming))

⁴⁴[https://en.wikipedia.org/wiki/Syntax_\(programming_languages\)](https://en.wikipedia.org/wiki/Syntax_(programming_languages))

⁴⁵<https://thewritepractice.com/why-you-need-to-be-using-oxford-commas/>

```
1 print( type(23) )      # int
2 print( type(3.14) )    # float
3 print( type("hello") ) # str
4
5 print( type("23") )     # str
6 print( type("3.24") )   # str
7
8 print( type(None) )     # NoneType
9 print( type(True) )     # bool
10 print( type(False) )   # bool
11
12 print( type([]) )      # list
13 print( type({}) )      # dict
14
15 print( type(hello) )    # NameError: name 'hello' is not defined
16 print("Still running")
```

```
1 Traceback (most recent call last):
2   File "python/examples/basics/types.py", line 15, in <module>
3     print( type(hello) )    # str
4 NameError: name 'hello' is not defined
```

- Strings must be enclosed in quotes.
- Numbers must be NOT enclosed in quotes.

Floating point limitation

```
1 print(0.1 + 0.2)    # 0.30000000000000004
```

- [floating point](#)⁴⁶

Value Types in Numpy

Numpy but also other programming languages might have them.

- int8
- int32
- float32
- float64
- ...

⁴⁶<https://docs.python.org/3/tutorial/floatingpoint.html>

Rectangular (numerical operations)

```
1 width = 23
2 height = 17
3 area = width * height
4 print(area)    # 391
```

Multiply string

```
1 width = "23"
2 height = "17"
3 area = width * height
4 print(area)
```

```
1 Traceback (most recent call last):
2   File "python/examples/basics/rectangular_strings.py", line 3, in <module>
3     area = width * height
4   TypeError: can't multiply sequence by non-int of type 'str'
```

Add numbers

```
1 a = 19
2 b = 23
3 c = a + b
4 print(c)    # 42
```

Add strings

```
1 a = "19"
2 b = "23"
3 c = a + b
4 print(c)    # 1923
```

Exercise: Calculations

- Extend the rectangular_basic.py from above to print both the area and the circumference of the rectangle.
- Write a script that has a variable holding the radius of a circle and prints out the area of the circle and the circumference of the circle.
- Write a script that has two numbers a and b and prints out the results of a+b, a-b, a*b, a/b

Solution: Calculations

```
1 width = 23
2 height = 17
3 area = width * height
4 print("The area is ", area)      # 391
5 circumference = 2 * (width + height)
6 print("The circumference is ", circumference)    # 80
```

```
1 r = 7
2 pi = 3.14
3 print("The area is ", r * r * pi)      # 153.86
4 print("The circumference is ", 2 * r * pi) # 43.96
```

```
1 import math
2
3 r = 7
4 print("The area is ", r * r * math.pi)      # 153.9380400258998
5 print("The circumference is ", 2 * r * math.pi) # 43.982297150257104
```

```
1 a = 3
2 b = 2
3
4 print(a+b)    # 5
5 print(a-b)    # 1
6 print(a*b)    # 6
7 print(a/b)    # 1.5
```

Second steps

Modules

```
1 import sys
2
3 print( sys.executable )           # /home/gabor/venv3/bin/python
4 print( sys.platform )             # linux
5 print( sys.argv[0] )              # examples/basics/modules.py
6 print( sys.version_info.major )   # 3
7
8 print( sys.getsizeof( 1 ) )        # 28
9 print( sys.getsizeof( 42 ) )       # 28
10 print( sys.getsizeof( 1.0 ) )      # 24
11
12 print( sys.getsizeof( "" ) )        # 49
13 print( sys.getsizeof( "a" ) )       # 50
14 print( sys.getsizeof( "ab" ) )      # 51
15 print( sys.getsizeof( "abcdefghij" ) ) # 59
```

A main function

```
1 def main():
2     print("Hello")
3     print("World")
```

This won't run as the main function is declared, but it is never called (invoked).

The main function - called

You could write your code in the main body of your Python file, but using functions and passing arguments to it will make your code easier to maintain and understand. Therefore I recommend that you always write every script with a function called “main”.

- Function definition starts with the **def** keyword, followed by the name of the new function (“main” in this case), followed by the list of **parameters in parentheses** (nothing in this case).

- The content or body of the function is then **indented** to the right.
- The function definition ends when the indentation stops.

```
1 def main():
2     print("Hello")
3     print("World")
4
5 print("before")
6 main()
7 print("after")
```

```
1 before
2 Hello
3 World
4 after
```

- Use a main function to avoid globals and better structure your code.
- Python uses **indentation** for blocks instead of curly braces, and it uses the colon : to start a block.

Indentation

- Standard recommendations: 4 spaces on every level.

Conditional main

```
1 def main():
2     print("Hello World")
3
4 if __name__ == "__main__":
5     main()
```

- We'll cover this later but in case you'd like, you can include this conditional execution of the main function.

Input - Output I/O

Input

- Keyboard (Standard Input, Command line, GUI)
- Mouse (Touch pad)
- Touch screen
- Files, Filesystem
- Network (e.g. in Web applications)

Output

- Screen
- File
- Network

print in Python 2

print is one of the keywords that changed between Python 2 and Python 3. In Python 2 it does not need parentheses, in Python 3 it is a function and it needs to have parentheses.

```
1 print "hello"
2 print "world"
3 print "Foo", "Bar"
```

```
1 hello
2 world
3 Foo Bar
```

```
1 print "hello",
2 print "world"
3 print "Foo", "Bar",
```

```
1 hello world
2 Foo Bar
```

No newline, but a space is added at the end of the output and between values.

```
1 import sys
2 sys.stdout.write("hello")
3 sys.stdout.write("world")
```

```
1 helloworld
```

write takes exactly one parameter

print in Python 3

```
1 print("hello")
2 print("world")
3 print("Foo", "Bar")
```

```
1 hello
2 world
3 Foo Bar
```

```
1 print("hello", end=" ")
2 print("world")
3 print("Foo", "Bar")
```

```
1 hello world
2 Foo Bar
```

end will set the character added at the end of each print statement.

```
1 print("hello", end="")
2 print("world")
3
4 print("Foo", "Bar", sep="")
5 print("END")
```

```
1 helloworld
2 FooBar
3 END
```

sep will set the character separating values.

print in Python 2 as if it was Python 3

```
1 from __future__ import print_function
2 print("hello", end="")
3 print("world")
```

```
1 helloworld
```

Exception: SyntaxError: Missing parentheses in call

What if we run some code with `print "hello"` using Python 3?

```
1 File "examples/basics/print.py", line 1
2     print "hello"
3         ^
4 SyntaxError: Missing parentheses in call to 'print'. Did you mean print("hello")?
```

Prompting for user input in Python 2

```
1  from __future__ import print_function
2
3  def main():
4      print("We have a question!")
5      name = raw_input('Your name: ')
6      print('Hello ' + name + ', how are you?')
7
8  main()
```

```
1  /usr/bin/python2 prompt2.py
2
3  We have a question!
4  Your name: Foo Bar
5  Hello Foo Bar, how are you?
```

What happens if you run this with Python 3 ?

```
1  /usr/bin/python3 prompt2.py

1  We have a question!
2  Traceback (most recent call last):
3    File "prompt2.py", line 7, in <module>
4      main()
5    File "prompt2.py", line 4, in main
6      name = raw_input('Your name: ')
7  NameError: name 'raw_input' is not defined
```

Prompting for user input in Python 3

In Python 3 the `raw_input()` function was replaced by the `input()` function.

```
1 def main():
2     print("We have a question!")
3     name = input('Your name: ')
4     print('Hello ' + name + ', how are you?')
5
6 main()
```

What happens if you run this using Python 2 ?

```
1 /usr/bin/python2 prompt3.py
```

```
1 We have a question!
2 Your name: Foo Bar
3 Your name: Traceback (most recent call last):
4   File "prompt3.py", line 5, in <module>
5     main()
6   File "prompt3.py", line 2, in main
7     name = input('Your name: ')
8   File "<string>", line 1
9     Foo Bar
10         ^
11 SyntaxError: unexpected EOF while parsing
```

```
1 We have a question!
2 Your name: Foo
3 Your name: Traceback (most recent call last):
4   File "prompt3.py", line 5, in <module>
5     main()
6   File "prompt3.py", line 2, in main
7     name = input('Your name: ')
8   File "<string>", line 1, in <module>
9 NameError: name 'Foo' is not defined
```

Python2 input or raw_input?

In Python 2 always use `raw_input()` and never `input()`.

Prompting both Python 2 and Python 3

```
1  from __future__ import print_function
2  import sys
3
4  def main():
5      if sys.version_info.major < 3:
6          name = raw_input('Your name: ')
7      else:
8          name = input('Your name: ')
9      print('Hello ' + name + ', how are you?')
10
11  main()
```

Add numbers entered by the user (oups)

```
1  def main():
2      a = input('First number: ')
3      b = input('Second number: ')
4      print(a + b)
5
6  main()
```

```
1  First number: 2
2  Second number: 3
3  23
```

When reading from the command line using `input()`, the resulting value is a string. Even if you only typed in digits. Therefore the addition operator `+` concatenates the strings.

Add numbers entered by the user (fixed)

```
1  def main():
2      a = input('First number: ')
3      b = input('Second number: ')
4      print(int(a) + int(b))
5
6  main()
```

```
1 First number: 2
2 Second number: 3
3 5
```

In order to convert the string to numbers use the `int()` or the `float()` functions. Whichever is appropriate in your situation.

How can I check if a string can be converted to a number?

- `stdtypes`⁴⁷

```
1 val = input("Type in a number: ")
2 print(val)
3 print(val.isdecimal())
4 print(val.isnumeric())
5
6 if val.isdecimal():
7     num = int(val)
8     print(num)
```

```
1 Type in a number: 42
2 True
3 True
4 42
```

- We'll talk about this later. For now assume that the user enters something that can be converted to a number.
- Use Regular Expressions (regexes) to verify that the input string looks like a number.
- Wrap the code in try-except block to catch any exception raised during the conversion.

Converting string to int

⁴⁷<https://docs.python.org/library/stdtypes.html>

```
1 a = "23"
2 print(a)          # 23
3 print( type(a) )  # <class 'str'>
4
5
6 b = int(a)
7 print(b)          # 23
8 print( type(b) )  # <class 'int'>
```

```
1 a = "42 for life"
2 print(a)          # 42 for life
3 print( type(a) )  # <class 'str'>
4
5 b = int(a)
6 print(b)
7 print( type(b) )
8
9 # Traceback (most recent call last):
10 #   File "converting_string_to_int.py", line 5, in <module>
11 #     b = int(a)
12 # ValueError: invalid literal for int() with base 10: '42 for life'
```

Converting float to int

```
1 a = 2.1
2 print( type(a) )  # <class 'float'>
3 print(a)          # 2.1
4
5 b = int(2.1)
6 print( type(b) )  # <class 'int'>
7 print(b)          # 2
```

```
1 a = "2.1"
2 print(a)          # 2.1
3 print( type(a) )  # <class 'str'>
4
5 b = int(a)
6 print(b)
7 print( type(b) )
8
9 # Traceback (most recent call last):

11 #     b = int(a)
12 # ValueError: invalid literal for int() with base 10: '2.1'
```

```
1 a = "2.1"
2 b = float(a)
3 c = int(b)
4 print(c)          # 2
5 print( type(a) )  # <class 'str'>
6 print( type(b) )  # <class 'float'>
7 print( type(c) )  # <class 'int'>
8
9 d = int( float(a) )
10 print(d)          # 2
11 print( type(d) )  # <class 'int'>
12
13 print( int( float(2.1) ) ) # 2
14 print( int( float("2") ) ) # 2
15 print( int( float(2) ) )   # 2
```

Conditionals: if

```
1 def main():
2     expected_answer = "42"
3     inp = input('What is the answer? ')
4
5     if inp == expected_answer:
6         print("Welcome to the cabal!")
7
8 main()
```

Conditionals: if - else

```
1 def main():
2     expected_answer = "42"
3     inp = input('What is the answer? ')
4
5     if inp == expected_answer:
6         print("Welcome to the cabal!")
7     else:
8         print("Read the Hitchhiker's guide to the galaxy!")
9
10 main()
```

Conditionals: if - else (other example)

```
1 def main():
2     a = input('First number: ')
3     b = input('Second number: ')
4
5     if int(b) == 0:
6         print("Cannot divide by 0")
7     else:
8         print("Dividing", a, "by", b)
9         print(int(a) / int(b))
10
11
12 main()
```

Conditionals: else if

```
1 def main():
2     a = input('First number: ')
3     b = input('Second number: ')
4
5     if a == b:
6         print('They are equal')
7     else:
8         if int(a) < int(b):
9             print(a + ' is smaller than ' + b)
10        else:
11            print(a + ' is bigger than ' + b)
12
13 main()
```

Conditionals: elif

```
1 def main():
2     a = input('First number: ')
3     b = input('Second number: ')
4
5     if a == b:
6         print('They are equal')
7     elif int(a) < int(b):
8         print(a + ' is smaller than ' + b)
9     else:
10        print(a + ' is bigger than ' + b)
11
12
13 main()
```

Ternary operator

```
1 x = 3
2 answer = 'positive' if x > 0 else 'negative'
3 print(answer)    # positive
4
5 x = -3
6 answer = 'positive' if x > 0 else 'negative'
7 print(answer)    # negative
```

```
1 x = 3
2 if x > 0:
3     answer = 'positive'
4 else:
5     answer = 'negative'
6 print(answer)    # positive
7
8 x = -3
9 if x > 0:
10    answer = 'positive'
11 else:
12    answer = 'negative'
13 print(answer)    # negative
```

Case or Switch in Python

- There is no case or switch statement in Python.

Exercise: Rectangular

- Write a script that will ask for the sides of a rectangular and print out the area.
- Provide error messages if either of the sides is negative.

```
1 python rect.py
2 Side: 3
3 Side: 4
4 The area is 12
```

Exercise: Calculator

Create a script that accepts 2 numbers and an operator (+, -, *, /), and prints the result of the operation.

```
1 python calc.py
2 Operand: 19
3 Operand: 23
4 Operator: +
5 Results: 42
```

Exercise: Standard Input

- In the previous exercises we expected the userinput to come in on the “Standard Input” aka. STDIN.
- If you would like to practice this more, come up with other ideas, try to solve them and tell me about the task. (in person or via e-mail.)
- (e.g. you could start building an interactive role-playing game.)

Solution: Area of rectangular

```
1 def main():
2     #length = 10
3     #width = 3
4
5     length = int(input('Length: '))
6     width = int(input('Width: '))
7
8     if length <= 0:
9         print("length is not positive")
10        return
11
12    if width <= 0:
13        print("width is not positive")
14        return
15
16    area = length * width
17    print("The area is ", area)
18
19 main()
```

Same in Python 2

```
1 from __future__ import print_function
2
3 def main():
4     #length = 10
5     #width = 3
6
7     length = int(raw_input('Length: '))
8     width = int(raw_input('Width: '))
9
10    if length <= 0:
11        print("length is not positive")
12        return
13
14    if width <= 0:
15        print("width is not positive")
16        return
17
18    area = length * width
19    print("The area is ", area)
20
21 main()
```

Solution: Calculator

```
1 def main():
2     a = float(input("Number: "))
3     b = float(input("Number: "))
4     op = input("Operator (+-*/): ")
5
6     if op == '+':
7         res = a+b
8     elif op == '-':
9         res = a-b
10    elif op == '*':
11        res = a*b
12    elif op == '/':
13        res = a/b
14    else:
15        print("Invalid operator: '{}'.format(op))
16        return
17
18    print(res)
19    return
20
21
22 main()
```

Same in Python 2

```
1 from __future__ import print_function
2
3 a = float(raw_input("Number: "))
4 b = float(raw_input("Number: "))
5 op = raw_input("Operator (+-*/): ")
6
7 if op == '+':
8     res = a+b
9 elif op == '-':
10    res = a-b
11 elif op == '*':
12    res = a*b
13 elif op == '/':
14    res = a/b
15 else:
```

```
16     print("Invalid operator: '{}'".format(op))
17     exit()
18
19
20 print(res)
```

Command line arguments

```
1  import sys
2
3  def main():
4      print(sys.argv)
5      print(sys.argv[0])
6      print(sys.argv[1])
7      print(sys.argv[2])
8
9  main()
```

```
1  $ python examples/basic/cli.py one two
```

```
1  ['examples/basics/cli.py', 'one', 'two']
2  examples/basics/cli.py
3  one
4  two
```

```
1  $ python examples/basic/cli.py
```

```
1  ['examples/basics/cli.py']
2  examples/basics/cli.py
3  Traceback (most recent call last):
4    File "examples/basics/cli.py", line 6, in <module>
5      print(sys.argv[1])
6  IndexError: list index out of range
```

Command line arguments - len

```
1 import sys
2
3 def main():
4     print(sys.argv)
5     print(len(sys.argv))
6
7 main()
```

Command line arguments - exit

```
1 import sys
2
3 def main():
4     if len(sys.argv) != 2:
5         exit("Usage: " + sys.argv[0] + " VALUE")
6     print("Hello " + sys.argv[1])
7
8 main()
```

```
1 echo %errorlevel%
2 echo $?
```

Exercise: Rectangular (argv)

- Change the above script that it will accept the arguments on the command line like this: `python rect.py 2 4`

Exercise: Calculator (argv)

- Create a script that accepts 2 numbers and an operator (+, -, *, /), on the command line and prints the result of the operation.
- `python calc.py 2 + 3`
- `python calc.py 6 / 2`
- `python calc.py 6 * 2`

Solution: Area of rectangular (argv)

```
1  import sys
2
3  def main():
4      if len(sys.argv) != 3:
5          exit("Needs 2 arguments: width length")
6
7      width = int( sys.argv[1] )
8      length = int( sys.argv[2] )
9
10     if length <= 0:
11         exit("length is not positive")
12
13     if width <= 0:
14         exit("width is not positive")
15
16     area = length * width
17     print("The area is ", area)
18
19 main()
```

Solution: Calculator eval

```
1  def main():
2      a = input("Number: ")
3      b = input("Number: ")
4      op = input("Operator (+-*/): ")
5
6      command = a + op + b
7      print(command)
8      res = eval(command)
9      print(res)
10
11 main()
```

```
1 $ python examples/basics/calculator_eval.py
2
3 Number: 2
4 Number: 3
5 Operator (+-*/): +
6 2+3
7 5
```

Solution: Calculator (argv)

```
1 import sys
2
3
4 def main():
5     if len(sys.argv) < 4:
6         exit("Usage: " + sys.argv[0] + " OPERAND OPERATOR OPERAND")
7
8     a = float(sys.argv[1])
9     b = float(sys.argv[3])
10    op = sys.argv[2]
11
12    if op == '+':
13        res = a + b
14    elif op == '-':
15        res = a - b
16    elif op == '*':
17        res = a * b
18    elif op == '/':
19        res = a / b
20    else:
21        print("Invalid operator: '{}'.format(op))
22        exit()
23
24    print(res)
25
26 main()
```

The multiplication probably won't work because the Unix/Linux shell replaces the `*` by the list of files in your current directory and thus the python script will see a list of files instead of the `*`.

This is not your fault as a programmer. It is a user error. The correct way to run the script is `python calc.py 2 '*' 3`.

Compilation vs. Interpretation

Compiled

- Languages: C, C++
- Development cycle: Edit, Compile (link), Run.
- Strong syntax checking during compilation and linking.
- Result: Stand-alone executable code.
- Need to compile to each platform separately. (Windows, Linux, Mac, 32bit vs 64bit).

Interpreted

- Shell, BASIC
- Development cycle: Edit, Run.
- Syntax check only during run-time.
- Result: we distribute the source code.
- Needs the right version of the interpreter on every target machine.

Both?

- Java (running on JVM - Java Virtual Machine)
- C# (running on CLR - Common Language Runtime)

Is Python compiled or interpreted?

There are syntax errors that will prevent your Python code from running

```
1 x = 2
2 print(x)
3
4 if x > 3
```

```
1 File "examples/other/syntax_error.py", line 4
2     if x > 3
3         ^
4 SyntaxError: invalid syntax
```

There are other syntax-like errors that will be only caught during execution

```
1 x = 2
2 print(x)
3 print(y)
4 y = 13
5 print(42)
```

```
1 2
2 Traceback (most recent call last):
3   File "compile.py", line 5, in <module>
4     print y
5 NameError: name 'y' is not defined
```

- Python code is first compiled to bytecode and then interpreted.
- CPython is both the compiler and the interpreter.
- Jython and IronPython are mostly just compiler to JVM and CLR respectively.

Flake8 checking

```
1 conda install flake8
2 pip install flake8
3
4 flake8 --ignore= compile.py
```

```
1 compile.py:3:7: F821 undefined name 'y'
2 compile.py:6:1: W391 blank line at end of file
```

Numbers

Numbers

```
1 a = 42    # decimal
2 h = 0xA   # 10 - hex          - starting with 0x
3 o = 0o11  # 9  - octal        - starting with 0o
4          # 011 works in Python 2.x but Python 3.x
5          # requires the o that works in
6          # (recent versions of) Python 2.x
7 b = 0b11  # 3  - binary numbers - starting with 0b
8
9 r = 2.3
10
11 print(a) # 42
12 print(h) # 10
13 print(o) # 9
14 print(b) # 3
15 print(r) # 2.3
```

In Python numbers are stored as decimals, but in the source code you can also use hexadecimal, octal, or binary notations.

This is especially useful if the domain you are programming in is using those kinds of numbers.

For example hardware engineers often talk in hexadecimal values.

In that case you won't need to constantly translate between the form used in the current domain and decimal numbers.

Operators for Numbers

```
1  a = 2
2  b = 3
3  c = 2.3
4
5  d = a + b
6  print(d)      # 5
7  print(a + b)  # 5
8  print(a + c)  # 4.3
9  print(b / a)  # 1.5 # see the __future__
10 print(b // a) # 1   # floor division
11 print(a * c)  # 4.6
12
13 print(a ** b) # 8   (power)
14
15 print(17 % 3) # 2   (modulus)
16
17 a += 7        # is the same as a = a + 7
18 print(a)      # 9
19
20 # a++         # SyntaxError: invalid syntax
21 # a--         # SyntaxError: invalid syntax
22
23 a += 1
24 print(a)      # 10
25 a -= 1
26 print(a)      # 9
```

There is no autoincrement (++) and autodecrement (–) in Python, because they can be expressed by += 1 and -= 1 respectively.

Integer division and the future

```
1  from __future__ import print_function
2
3  print(3/2)
```

```

1 $ python divide.py
2 1
3
4 $ python3 divide.py
5 1.5

```

```

1 from __future__ import print_function
2 from __future__ import division
3
4 print(3/2)      # 1.5

```

If you need to use Python 2, remember that by default division is integer based so $3/2$ would return 1.

Importing the 'division' directive from **future** changes this to the behavior that we usually expect $3/2$ being 1.5.

This is also the behavior we have in Python 3.

In case you already use Python 3 and would like to get the “old” behavior, that is to get the integer part of the division, you can always call the “int” function: `int(b/a)`.

Pseudo Random Number

```

1 import random
2
3 a = random.random()
4 print(a) # 0.5648261676148922 a value between 0.0 <= < 1.0
5 print(random.random())
6 print(random.random())

```

- [random](http://docs.python.org/library/random.html)⁴⁸
- [Pseudo random generator](https://en.wikipedia.org/wiki/Pseudorandom_number_generator)⁴⁹

Fixed random numbers

⁴⁸<http://docs.python.org/library/random.html>

⁴⁹https://en.wikipedia.org/wiki/Pseudorandom_number_generator

```
1 import random
2
3 random.seed(37)
4
5 print(random.random()) # 0.6820045605879779
6 print(random.random()) # 0.09160260807956389
7 print(random.random()) # 0.6178163488614024
```

Rolling dice - randrange

```
1 import random
2
3 print( 1 + int( 6 * random.random() ))
4
5 print(random.randrange(1, 7))
6
7 # One of the following: 1, 2, 3, 4, 5, 6
```

Random choice

```
1 import random
2
3 letter = "abcdefghijklmno"
4 print(random.choice(letters))    # pick one of the letters
5
6 fruits = ["Apple", "Banana", "Peach", "Orange", "Durian", "Papaya"]
7 print(random.choice(fruits))
8     # pick one of the fruits
```

built-in method

- A common mistake. Not calling the method.

```
1 import random
2
3 rnd = random.random
4 print(rnd)      # <built-in method random of Random object at 0x124b508>
5
6
7 y = rnd()
8 print(y)        # 0.7740737563564781
```

When you see a string like the above “built-in method ...” you can be almost certainly sure that you have forgotten the parentheses at the end of a method call.

Exception: TypeError: ‘module’ object is not callable

- A common mistake. Calling the class and not the method.

```
1 import random
2
3 print("hello")
4 x = random()
5 print(x)
```

```
1 Traceback (most recent call last):
2   File "examples/numbers/rnd.py", line 3, in <module>
3     x = random()
4 TypeError: 'module' object is not callable
```

Fixing the previous code

```
1 import random
2
3 x = random.random()
4 print(x)
```

```
1 from random import random
2
3 x = random()
4 print(x)
```

Exception: AttributeError: module 'random' has no attribute

- A common mistake. Using the wrong filename.

This works fine:

```
1 print("Hello World")
```

This gives an error

```
1 import random
2 print(random.random())
```

```
1 Traceback (most recent call last):
2   File "rnd.py", line 2, in <module>
3     print(random.random())
4   AttributeError: module 'random' has no attribute 'random'
```

Make sure the names of your files are not the same as the names of any of the python packages.

Exercise: Number guessing game - level 0

Level 0

- Using the random module the computer “thinks” about a whole number between 1 and 20.
- The user has to guess the number. After the user types in the guess the computer tells if this was bigger or smaller than the number it generated, or if was the same.
- The game ends after just one guess.

Level 1-

- Other levels in the next chapter.

Exercise: Fruit salad

- Write a script that will pick 3 fruits from a list of fruits like the one we had in one of the earlier slides. Print the 3 names.
- Could you make sure the 3 fruits are different?

```
1 fruits = ["Apple", "Banana", "Peach", "Orange", "Durian", "Papaya"]
```

Solution: Number guessing game - level 0

```
1 import random
2
3 hidden = random.randrange(1, 21)
4 print("The hidden values is", hidden)
5
6 user_input = input("Please enter your guess: ")
7 print(user_input)
8
9 guess = int(user_input)
10 if guess == hidden:
11     print("Hit!")
12 elif guess < hidden:
13     print("Your guess is too low")
14 else:
15     print("Your guess is too high")
```

Solution: Fruit salad

```
1 import random
2
3 fruits = ["Apple", "Banana", "Peach", "Orange", "Durian", "Papaya"]
4 salad = random.sample(fruits, 3)
5 print(salad)
```

Boolean

if statement again

```
1 x = 2
2
3 if x == 2:
4     print("it is 2")
5 else:
6     print("it is NOT 2")
7
8
9 if x == 3:
10    print("it is 3")
11 else:
12    print("it is NOT 3")
13
14 # it is 2
15 # it is NOT 3
```

True and False

- True and False are real boolean values.

```
1 x = 2
2
3 v = x == 2
4 print(v)
5 if v:
6     print(v, "is true - who would thought? ")
7
8 v = x == 3
9 print(v)
10 if v:
11     print(v, "is true - who would thought? ")
12 else:
```

```
13     print(v, "is false - who would thought? ")
14
15 # True
16 # True is true - who would thought?
17 # False
18 # False is false - who would thought?
```

Boolean

```
1  x = 23
2
3  if x:
4      print("23 is true")
5
6  y = 0
7  if y:
8      print("0 is true")
9  else:
10     print("0 is false")
11
12 # 23 is true
13 # 0 is false
```

True and False values in Python

- None
- 0
- "" (empty string)
- False
- []
- {}
- ()

Everything else is true.

```
1 values = [None, 0, "", False, [], (), {}, "0", True]
2
3 for v in values:
4     if v:
5         print("True value: ", v)
6     else:
7         print("False value: ", v)
8
9 # False value:  None
10 # False value:  0
11 # False value:
12 # False value:  False
13 # False value:  []
14 # False value:  ()
15 # False value:  {}
16 # True value:   0
17 # True value:   True
```

None is like undef or Null or Nill in other languages.

Comparision operators

```
1 ==          equal
2 !=          not equal
3
4 <           less than
5 <=          less than or equal
6 >           greater than
7 >=          greater than or equal
```

```
1 a = "42"
2 b = 42
3
4 print(a == b)      # False
5 print(a != b)      # True
6 print(b == 42.0)   # True
7
8 print(None == None) # True
9 print(None == False) # False
```

Do NOT Compare different types

```
1 x = 12
2 y = 3
3 print(x > y)  # True
4
5 x = "12"
6 y = "3"
7 print(x > y)  # False
8
9 x = "12"
10 y = 3
11 print(x > y)  # True
12
13 x = 12
14 y = "3"
15 print(x > y)  # False
```

In Python 2 please be careful and only compare the same types.
Otherwise the result will look strange.

```
1 True
2 False
3 True
4 False
```

In Python 3, comparing different types raises exception:

```
1 True
2 False
3 Traceback (most recent call last):
4   File "examples/other/compare.py", line 6, in <module>
5     print(x > y)      # True
6   TypeError: '>' not supported between instances of 'str' and 'int'
```

Boolean operators

- and
- or
- not

```

1  if COND:
2      do something
3  else:
4      do something other
5
6  if not COND:
7      do something other
8
9  if COND1 and COND2:
10     do something
11
12 if COND1 or COND2:
13     do something
14
15 if COND1 and not COND2:
16     do something

```

Boolean truth tables

1	COND1 and COND2	Result
2	True True	True
3	True False	False
4	False True	False
5	False False	False

1	COND1 or COND2	Result
2	True True	True
3	True False	True
4	False True	True
5	False False	False

1	not COND	Result
2	True	False
3	False	True

Short circuit

```
1 def check_money():
2     return money > 1000000
3
4 def check_salary():
5     salary += 1
6     return salary >= 1000
7
8 while True:
9     if check_money() or check_salary():
10        print("I can live well")
```

Short circuit fixed

```
1 def check_money():
2     return money > 1000000
3
4 def check_salary():
5     salary += 1
6     return salary >= 1000
7
8 while True:
9     has_good_money = check_money()
10    has_good_salary = check_salary()
11
12    if has_good_money or has_good_salary:
13        print("I can live well")
```

Incorrect use of conditions

In your normal speech you could probably say something like “If status_code is 401 or 302, do something.”.

Meaning status_code can be either 401 or 302.

If you tried to translate this into code directly you would write something like this:

```
1 if status_code == 401 or 302:
2     pass
```

However this is incorrect. This condition will be always true as this is actually same as if you wrote:
`if (status_code == 401) or (302)` so it will compare `status_code` to 401, and it will separately check if 302 is True, but any number different from 0 is considered to be True so the above expression will always be True.

What you probably meant is this:

```
1 if status_code == 401 or status_code == 302:  
2     pass
```

Alternative way:

An alternative way to achieve the same results would be though probbaly at this point we have not learned the “in” operator, nor lists (comma separated values in square brackets):

```
1 if status_code in [401, 302]  
2     pass
```

Exercise: compare numbers

- Ask the user to enter two numbers and tell us which one is bigger.

Exercise: compare strings

- Ask the user to enter two strings
- Then ask the user to select if she wants to compare them based on ASCII or based on their length
- Then tell us which one is bigger.

```
1  Input a string: (user types string and ENTER)
2  Input another string: (user types string and ENTER)
3  How to compare:
4  1) ASCII
5  2) Length
6  (user types 1 or 2 and ENTER)
```

Solution: compare numbers

```
1  a_in = input("Please type in a string: ")
2  b_in = input("Please type in another string: ")
3  print("How to compare:")
4  print("1) ASCII")
5  print("2) Length")
6  how = input()
7
8  if how == '1':
9      first = a_in > b_in
10     second = a_in < b_in
11 elif how == '2':
12     first = len(a_in) > len(b_in)
13     second = len(a_in) < len(b_in)
14
15 if first:
16     print("First number is bigger")
17 elif second:
18     print("First number is smaller")
19 else:
20     print("They are equal")
```

Solution: compare strings

```
1 a_in = input("Please type in a string: ")
2 b_in = input("Please type in another string: ")
3 print("How to compare:")
4 print("1) ASCII")
5 print("2) Length")
6 how = input()
7
8 if how == '1':
9     first = a_in > b_in
10    second = a_in < b_in
11 elif how == '2':
12     first = len(a_in) > len(b_in)
13     second = len(a_in) < len(b_in)
14
15 if first:
16     print("First number is bigger")
17 elif second:
18     print("First number is smaller")
19 else:
20     print("They are equal")
```

Strings

Single quoted and double quoted strings

In Python, just as in most of the programming languages you must put any free text inside a pair of quote characters.

Otherwise Python will try to find meaning in the text.¹

These pieces of texts are called “strings”.

In Python you can put string between two single quotes: ‘’ or between two double quotes: “”. Which one does not matter.

```
1 soup = "Spiced carrot & lentil soup"
2 salad = 'Ceasar salad'
3
4 print(soup)
5 print(salad)
```

```
1 Spiced carrot & lentil soup
2 Ceasar salad
```

Long lines

```
1 text = "abc" "def"
2 print(text)
3
4 other = "abcdef"
5 print(other)
6
7
8 long_string = "one" "two" "three"
9 print(long_string)
10
11 short_rows = "one" \
```

```
12     "two" \
13     "three"
14 print(short_rows)
15
16 long_string = "first row second row third row"
17 print(long_string)
18
19 shorter = "first row \
20 second row \
21 third row"
22 print(shorter)
```

```
1 abcdef
2 abcdef
3 onetwothree
4 onetwothree
5 first row second row third row
6 first row second row third row
```

Triple quoted strings (multiline)

If you would like to create a string the spreads on multiple lines, there is a possibility to put the text between 3 quotes on both sides. Either *23 single-quotes* or *23 double-quotes*.

```
1 text = """first row
2 second row
3 third row"""
4
5 print(text)
```

Can spread multiple lines.

```
1 first row
2 second row
3 third row
```

String length (len)

The `len` function returns the length of the string in number of characters.

```
1 line = "Hello World"
2 hw = len(line)
3 print(hw) # 11
4
5 text = """Hello
6 World"""
7 print(len(text)) # 12
```

String repetition and concatenation

You might be used to the fact that you can only multiply numbers, but in python you can also “multiply” a string by a number.

It is called repetition. In this example we have a string “Jar “ that we repeat twice.

We can also add two strings to concatenate them together.

I don’t think the repetition operator is used very often, but in one case it could come very handy. When you are writing some text report and you’d like to add a long line of dashes that would be exactly the same length as your title.

```
1 name = 2 * 'Jar '
2 print(name) # Jar Jar
3
4 full_name = name + 'Binks'
5 print(full_name) # Jar Jar Binks
6
7
8 title = "We have some title"
9 print(title)
10 print('-' * len(title))
11
12 # We have some title
13 # -----
```

A character in a string

```
1 text = "Hello World"
2
3 a = text[0]
4 print(a)      # H
5
6 b = text[6]
7 print(b)      # W
```

String slice (instead of substr)

```
1 text = "Hello World"
2
3 b = text[1:4]
4 print(b)      # ell
5
6 print(text[2:]) # llo World
7 print(text[:2]) # He
8
9 start = 1
10 end = 4
11 print(text[start:end]) # ell
```

Change a string

In Python strings are “immutable”, meaning you cannot change them. You can replace a whole string in a variable, but you cannot change it.

In the following example we wanted to replace the 3rd character (index 2), and put “Y” in place. This raised an exception

```
1 text = "abcd"
2 print(text)      # abcd
3
4 text[2] = 'Y'
5
6 print("done")
7 print(text)
```

```
1 abcd
2 Traceback (most recent call last):
3   File "string_change.py", line 4, in <module>
4     text[2] = 'Y'
5   TypeError: 'str' object does not support item assignment
```

Replace part of a string

- Strings in Python are **immutable** - they never change.

How to change a string

```
1 text = "abcd"
2 print(text)      # abcd
3
4 text = text[:2] + 'Y' + text[3:]
5 print(text)      # abYd
```

String copy

```
1 text = "abcd"
2 print(text)      # abcd
3
4 text = text + "ef"
5 print(text)      # abcdef
6
7 other = text
8 print(other)     # abcdef
9 text = "xyz"
10 print(text)     # xyz
11 print(other)    # abcdef
```

When assigning a variable pointing a string, the new variable is pointing to the same string..
If we then assign some other string to either of the variables, then they will point to two different strings.

String functions and methods (len, upper, lower)

```
1 a = "xYz"
2 print(len(a))    # 3
3
4 b = a.upper()
5 print(b)         # XYZ
6 print(a)         # xYz    - immutable!
7 print(a.lower()) # xyz
```

- Type `dir("")` in the REPL to get the list of string methods.
- List of [built-in functions](http://docs.python.org/library/functions.html)⁵⁰.
- List of [string methods](http://docs.python.org/library/string.html)⁵¹.

index in string

⁵⁰<http://docs.python.org/library/functions.html>

⁵¹<http://docs.python.org/library/string.html>

```
1 text = "The black cat climbed the green tree."
2 print(text.index("bl"))      # 4
3 print(text.index("The"))     # 0
4 print(text.index("dog"))

1 4
2 0
3 Traceback (most recent call last):
4   File "examples/strings/index.py", line 6, in <module>
5     print a.index("dog")      # -1
6 ValueError: substring not found
```

index in string with range

```
1 text = "The black cat climbed the green tree."
2 print(text.index("c"))       # 7
3 print(text.index("c", 8))    # 10
4
5 print(text.index("gr", 8))    # 26
6 print(text.index("gr", 8, 16))

1 7
2 10
3 26
4 Traceback (most recent call last):
5   File "examples/strings/index2.py", line 8, in <module>
6     print a.index("gr", 8, 16)
7 ValueError: substring not found
```

rindex in string with range

```
1 text = "The black cat climbed the green tree."
2 print(text.rindex("c"))          # 14
3 print(text.rindex("c", 8))       # 14
4 print(text.rindex("c", 8, 13))   # 10
5
6 print(text.rindex("gr", 8))       # 26
7 print(text.rindex("gr", 8, 16))

1 14
2 14
3 10
4 26
5 Traceback (most recent call last):
6   File "examples/strings/rindex.py", line 10, in <module>
7     print(a.rindex("gr", 8, 16))
8   ValueError: substring not found
```

find in string

Alternatively use find and rfind that will return -1 instead of raising an exception.

```
1 text = "The black cat climbed the green tree."
2 print(text.find("bl"))           # 4
3 print(text.find("The"))          # 0
4 print(text.find("dog"))          # -1
5
6 print(text.find("c"))            # 7
7 print(text.find("c", 8))         # 10
8
9 print(text.find("gr", 8))        # 26
10 print(text.find("gr", 8, 16))   # -1
11
12
13 print(text.rfind("c", 8))       # 14
```

Find all in the string

Later, when we learned loops.

in string

Check if a substring is **in** the string?

```
1 txt = "hello world"
2 if "wo" in txt:
3     print('found wo')
4
5 if "x" in txt:
6     print("found x")
7 else:
8     print("NOT found x")
```

```
1 found wo
2 NOT found x
```

index if in string

```
1 sub = "cat"
2 txt = "The black cat climbed the green tree"
3
4 if sub in txt:
5     loc = txt.index(sub)
6     print(sub + " is at " + str(loc))
7
8 sub = "dog"
9 if sub in txt:
10    loc = txt.index(sub)
11    print(sub + " is at " + str(loc))
12
13 # cat is at 10
```

raw strings

```

1  # file_a = "c:\Users\Foobar\readme.txt"
2  # print(file_a)
3
4  # Python2: eadme.txtFoobar
5  # Python3:
6  #   File "examples/strings/raw.py", line 6
7  #       file_a = "c:\Users\Foobar\readme.txt"
8  #           ^
9  # SyntaxError: (unicode error) 'unicodeescape' codec
10 #   can't decode bytes in position 2-3: truncated \UXXXXXXXX escape
11
12
13 file_b = "c:\\Users\\Foobar\\readme.txt"
14 print(file_b)  # c:\Users\Foobar\readme.txt
15
16 file_c = r"c:\Users\Foobar\readme.txt"
17 print(file_c)  # c:\Users\Foobar\readme.txt
18
19 text = r"text \n \d \s \ and more"
20 print(text)    # text \n \d \s \ and more

```

Escape sequences are kept intact and not escaped. Used in regexes.

ord

- `ord`⁵⁶

```

1  print( ord('a') )    # 97
2  print( ord('=') )    # 61
3  print( ord('\r') )   # 13
4  print( ord('\n') )   # 10
5  print( ord(' ') )    # 32
6
7  print( ord('á') )    # 225
8  print( ord('ó') )    # 243
9  print( ord('Π') )    # 1488

```

⁵⁶<https://docs.python.org/3/library/functions.html#ord>

ord in a file

```
1 import sys
2
3 filename = sys.argv[1]
4
5 with open(filename) as fh:
6     content = fh.read()
7
8 for c in content:
9     print(ord(c))
```

Exercise: one string in another string

Write script that accepts two strings and tells if one of them can be found in the other and where?

Exercise: to ASCII CLI

Write script that gets a character on the command line and prints out the ascii code of it.

Maybe even:

Write script that gets a string on the command line and prints out the ascii code of each character.

Exercise: from ASCII CLI

Write script that accepts a number on the command line and prints the character represented by that number.

Solution: one string in another string

```
1 import sys
2
3 if len(sys.argv) != 3:
4     exit(f"Usage: {sys.argv[0]} short-STRING long-STRING")
5
6 string = sys.argv[1]
7 text = sys.argv[2]
8
9 if string in text:
10     loc = text.index(string)
11     print(string, "can be found in ", text, "at", loc)
12 else:
13     print(string, "can NOT be found in ", text)
```

Solution: compare strings

```
1 mode = input("Mode of comparision: [length|ascii|")
2 if mode != "length" and mode != "ascii":
3     print("Not good")
4     exit()
5
6 str1 = input("String 1:")
7 str2 = input("String 2:")
8
9 if mode == "length":
10     print(len(str1) > len(str2))
11 elif mode == "ascii":
12     print(str1 > str2)
```

Solution: to ASCII CLI

```
1 import sys
2
3 if len(sys.argv) != 2:
4     exit(f"Usage: {sys.argv[0]} CHARACTER")
5
6 print( ord( sys.argv[1]) )
```

```
1 import sys
2
3 if len(sys.argv) != 2:
4     exit(f"Usage: {sys.argv[0]} STRING")
5
6 for cr in sys.argv[1]:
7     print( ord( cr ) )
```

Solution: from ASCII CLI

```
1 import sys
2
3 if len(sys.argv) != 2:
4     exit(f"Usage: {sys.argv[0]} NUMBER")
5
6 print( chr( int(sys.argv[1]) ) )
```

Loops

Loops: for-in and while

- **for in** - to iterate over a well defined list of values. (characters, range of numbers, shopping list, etc.)
- **while** - repeat an action till some condition is met. (or stopped being met)

for-in loop on strings

```
1 txt = 'hello world'
2 for c in txt:
3     print(c)
```

```
1 h
2 e
3 l
4 l
5 o
6
7 w
8 o
9 r
10 l
11 d
```

for-in loop on list

```
1 for fruit in ["Apple", "Banana", "Peach", "Orange", "Durian", "Papaya"]:
2     print(fruit)
```

```
1 Apple
2 Banana
3 Peach
4 Orange
5 Durian
6 Papaya
```

for-in loop on range

```
1 for i in range(3, 7):
2     print(i)
```

```

8     print(total)
9 KeyboardInterrupt
```

- Don't do this!
- Make sure there is a proper end-condition. (exit-condition)
- Use Ctrl-C to stop it

While with complex expression

```
1 import random
2
3 total = 0
4 while (total < 10000000) and (total % 17 != 1) and (total ** 2 % 23 != 7):
5     print(total)
6     total += random.randrange(20)
7
8 print("done")
```

While with break

```
1 import random
2
3 total = 0
4 while total < 10000000:
5     print(total)
6     total += random.randrange(20)
7
8     if total % 17 == 1:
9         break
10
11     if total ** 2 % 23 == 7:
12         break
13
14 print("done")
```

While True

```
1 import random
2
3 total = 0
4 while True:
5     print(total)
6     total += random.randrange(20)
7
8     if total >= 10000000:
9         break
10
11    if total % 17 == 1:
12        break
13
14    if total ** 2 % 23 == 7:
15        break
16
17 print("done")
```

Duplicate input call

```
1 id_str = input("Type in your ID: ")
2
3 while len(id_str) != 9:
4     id_str = input("Type in your ID")
5
6 print("Your ID is " + id_str)
```

Eliminate duplicate input call

```
1 while True:
2     id_str = input("Type in your ID: ")
3     if len(id_str) == 9:
4         break
5
6 print("Your ID is " + id_str)
```

do while loop

There is no `do ... while` in Python but we can write code like this to have similar effect.

```
1 while True:
2     answer = input("What is the meaning of life? ")
3     if answer == '42':
4         print("Yeeah, that's it!")
5         break
6
7 print("done")
```

while with many continue calls

```
1 while True:
2     line = get_next_line()
3
4     if last_line:
5         break
6
7     if line_is_empty:
8         continue
9
10    if line_has_an_hash_at_the_beginning: # #
11        continue
12
13    if line_has_two_slashes_at_the_beginning: # //
14        continue
15
16    do_the_real_stuff
```

Break out from multi-level loops

Not supported in Python. “If you feel the urge to do that, your code is probably too complex. create functions!”

Exit vs return vs break and continue

- **exit** will stop your program no matter where you call it.
- **return** will return from a function (it will stop the specific function only)
- **break** will stop the current “while” or “for” loop
- **continue** will stop the current iteration of the current “while” or “for” loop

Exercise: Print all the locations in a string

Given a string like “The black cat climbed the green tree.”, print out the location of every “c” character.

Exercise: Number guessing game

Level 0

- Using the random module the computer “thinks” about a whole number between 1 and 20.
- The user has to guess the number. After the user types in the guess the computer tells if this was bigger or smaller than the number it generated, or if was the same.
- The game ends after just one guess.

Level 1

- The user can guess several times. The game ends when the user guessed the right number.

Level 2

- If the user hits ‘x’, we leave the game without guessing the number.

Level 3

- If the user presses ‘s’, show the hidden value (cheat)

Level 4

- Soon we’ll have a level in which the hidden value changes after each guess. In order to make that mode easier to track and debug, first we would like to have a “debug mode”.
- If the user presses ‘d’ the game gets into “debug mode”: the system starts to show the current number to guess every time, just before asking the user for new input.
- Pressing ‘d’ again turns off debug mode. (It is a toggle each press on “d” changes the value to the other possible value.)

Level 5

- The ‘m’ button is another toggle. It is called ‘move mode’. When it is ‘on’, the hidden number changes a little bit after every step (+/-2). Pressing ‘m’ again will turn this feature off.

Level 6

- Let the user play several games.
- Pressing ‘n’ will skip this game and start a new one. Generates a new number to guess.

Exercise: MasterMind

Implement the MasterMind game.

The computer “thinks” a number with 4 different digits. You guess which digits. For every digit that matched both in value, and in location the computer gives you a *. For every digit that matches in value, but not in space the computer gives you a +. Try to guess the given number in as few guesses as possible.

```
1 Computer: 2153
2 You:      2467 *
3 You:      2715 *++
```

Exercise: Count unique characters

Given a string on the command line, count how many different characters it has.

```
1 python count_unique.py abcdaaa
2 4
```

Solution: Print all the locations in a string

```
1 text = "The black cat climbed the green tree."
2 start = 0
3 while True:
4     loc = text.find("c", start)
5     if loc == -1:
6         break
7     print(loc)
8     start = loc + 1
```

Solution 1 for Number Guessing

```
1  import random
2
3  hidden = random.randrange(1, 201)
4  while True:
5      user_input = input("Please enter your guess[x]: ")
6      print(user_input)
7
8      if user_input == 'x':
9          print("Sad to see you leaving early")
10         exit()
11
12     guess = int(user_input)
13     if guess == hidden:
14         print("Hit!")
15         break
16
17     if guess < hidden:
18         print("Your guess is too low")
19     else:
20         print("Your guess is too high")
```

Solution for Number Guessing (debug)

```
1  import random
2
3  hidden = random.randrange(1, 201)
4  debug = False
5  while True:
6      if debug:
7          print("Debug: ", hidden)
8
9      user_input = input("Please enter your guess [x|s|d]: ")
10     print(user_input)
11
12     if user_input == 'x':
13         print("Sad to see you leaving early")
14         exit()
15
16     if user_input == 's':
17         print("The hidden value is ", hidden)
18         continue
19
```

```
20     if user_input == 'd':
21         debug = not debug
22         continue
23
24     guess = int(user_input)
25     if guess == hidden:
26         print("Hit!")
27         break
28
29     if guess < hidden:
30         print("Your guess is too low")
31     else:
32         print("Your guess is too high")
```

Solution for Number Guessing (move)

```
1  import random
2
3  hidden = random.randrange(1, 201)
4  debug = False
5  move = False
6  while True:
7      if debug:
8          print("Debug: ", hidden)
9
10     if move:
11         mv = random.randrange(-2, 3)
12         hidden = hidden + mv
13
14     user_input = input("Please enter your guess [x|s|d|m]: ")
15     print(user_input)
16
17     if user_input == 'x':
18         print("Sad to see you leaving early")
19         exit()
20
21     if user_input == 's':
22         print("The hidden value is ", hidden)
23         continue
24
25     if user_input == 'd':
26         debug = not debug
```

```
27         continue
28
29     if user_input == 'm':
30         move = not move
31         continue
32
33     guess = int(user_input)
34     if guess == hidden:
35         print("Hit!")
36         break
37
38     if guess < hidden:
39         print("Your guess is too low")
40     else:
41         print("Your guess is too high")
```

Solution for Number Guessing (multi-game)

```
1  import random
2
3  debug = False
4  move = False
5  while True:
6      print("\nWelcome to another Number Guessing game")
7      hidden = random.randrange(1, 201)
8      while True:
9          if debug:
10             print("Debug: ", hidden)
11
12             if move:
13                 mv = random.randrange(-2, 3)
14                 hidden = hidden + mv
15
16             user_input = input("Please enter your guess [x|s|d|m|n]: ")
17             print(user_input)
18
19             if user_input == 'x':
20                 print("Sad to see you leaving early")
21                 exit()
22
23             if user_input == 's':
24                 print("The hidden value is ", hidden)
```

```
25         continue
26
27     if user_input == 'd':
28         debug = not debug
29         continue
30
31     if user_input == 'm':
32         move = not move
33         continue
34
35     if user_input == 'n':
36         print("Giving up, eh?")
37         break
38
39     guess = int(user_input)
40     if guess == hidden:
41         print("Hit!")
42         break
43
44     if guess < hidden:
45         print("Your guess is too low")
46     else:
47         print("Your guess is too high")
```

Solution: MasterMind

```
1  import random
2
3  width = 4
4  USED = '_'
5
6  hidden = random.sample(range(10), width)
7  # print(hidden)
8
9  while True:
10     # print(hidden)
11
12     inp = input("your guess ({} digits):".format(width))
13     if inp == 'x':
14         print("Bye")
15         exit()
16     if len(inp) != width:
```

```
17         print("We need exactly {} characters".format(width))
18         continue
19
20     guess = list(map(int, inp))
21     # print(guess)
22
23     if hidden == guess:
24         print("Match!")
25         break
26
27     my_hidden = hidden[:]
28     my_guess = guess[:]
29
30     result = ''
31     for i in range(width):
32         if my_hidden[i] == my_guess[i]:
33             result += '*'
34             my_hidden[i] = USED
35             my_guess[i] = USED
36     for i in range(width):
37         if my_guess[i] == USED:
38             continue
39         if my_guess[i] in my_hidden:
40             loc = my_hidden.index(my_guess[i])
41             my_hidden[loc] = USED
42             guess[i] = USED
43             result += '+'
44
45     print(''.join(result))
```

Solution: Count unique characters

```
1 import sys
2
3 s = sys.argv[1]
4
5 unique = ''
6 for c in s:
7     if c not in unique:
8         unique += c
9
10 print(len(unique))
```

```
1 import sys
2
3 s = sys.argv[1]
4
5 print(len(set(s)))
```

MasterMind to debug

Debug the following version of the MasterMind game.

```
1 import random
2
3
4 def number_generator():
5     y = [0, 0, 0, 0]
6
7     for i in range(0, 4):
8         y[i] = random.randrange(0, 10)
9         # print(y)
10        if i:
11            number += str(y[i])
12        else:
13            number = str(y[i])
14        # print(number)
15    return number
16
17
18 def user_input():
19     x = input("Type in 4 digits number:")
20     if len(x) == 4:
```

```
21         return x
22     else:
23         print("wrong input")
24         user_input()
25
26
27 def string_compare(x, y):
28     r = 0
29     q = 0
30     for i in range(0, 4):
31         if x[i] == y[i]:
32             r += 1
33             continue
34         for j in range(0, 4):
35             if x[i] == y[j]:
36                 if i == j:
37                     continue
38                 else:
39                     q += 1
40                     break
41     return r, q
42
43
44 def print_result(r):
45     print("")
46     for i in range(0, r[0]):
47         print("*", end="")
48     for i in range(0, r[1]):
49         print("+", end="")
50     print("\n")
51
52
53 def main():
54     comp = number_generator()
55     result = 0
56     while True:
57         user = user_input()
58         result = string_compare(comp, user)
59         print_result(result)
60         # print(result)
61         if result[0] == 4:
62             print("Correct!")
63             return
```

64

65

66 `main()`

PyCharm

PyCharm Intro

- IDE
- Introspection
- Running, Debugging

PyCharm Project

- At the opening create a new project (directory + Python version)
- File/New Project

PyCharm Files

- New file on Mac: Click on the project on the left hand side / Right-Click / New / File; Windows, Linux: Alt-Insert
- PyCharm Python console - see next slide
- Change Python on Mac: PyCharm / Preferences / Project: (name) / Project Interpreter
- Later File/New also starts to work.

PyCharm - run code

- Run/Run
- Set command line parameters
- Set environment variables
- Run/Debug (but set breakpoints before)

PyCharm Python console at the bottom left

```
1  2 + 3
2  x = 2
3  print(x)
4  def f(x, y):
5      return x+y
6
7  f(4, 5)
```

Refactoring example (with and without pycharm)

- Change variable name (in scope only)
- Extract method

Formatted printing

format - sprintf

```
1 age = 42.12
2 name = 'Foo Bar'
3
4 str_concatenate = "The user " + name + " was born " + str(age) + " years ago."
5 print(str_concatenate)
6
7 str_percentage = "The user %s was born %s years ago." % (name, age)
8 print(str_percentage)
9
10 str_format = "The user {} was born {} years ago.".format(name, age)
11 print(str_format)
12
13 str_f_string = f"The user {name} was born {age} years ago."
14 print(str_f_string)
```

```
1 The user Foo Bar was born 42.12 years ago.
2 The user Foo Bar was born 42.12 years ago.
3 The user Foo Bar was born 42.12 years ago.
4 The user Foo Bar was born 42.12 years ago.
```

- When using % to print more than one values, put the values in parentheses forming a tuple.
- In version 2.6 and below you need to write etc, as a placeholder of the format method.
- f-string are from Python 3.6

Examples using format - indexing

```
1 txt = "Foo Bar"
2 num = 42.12
3
4 print("The user {} was born {} years ago.".format(txt, num))
5 print("The user {0} was born {1} years ago.".format(txt, num))
6 print("The user {1} was born {0} years ago.".format(num, txt))
7
8
9 print("{0} is {0} and {1} years old.".format(txt, num))
```

```
1 The user Foo Bar was born 42.12 years ago.
2 The user Foo Bar was born 42.12 years ago.
3 The user Foo Bar was born 42.12 years ago.
4 Foo Bar is Foo Bar and 42.12 years old.
```

Examples using format with names

```
1 txt = "Foo Bar"
2 num = 42.12
3
4 print("The user {name} was born {age} years ago.".format(name = txt, age = num))

1 The user Foo Bar was born 42.12 years ago.
```

Format columns

In this example we use a list of lists that we have not learned yet, but don't worry about that for now.

Focus on the output of the two print statements.

```

1 data = [
2     ["Foo Bar", 42],
3     ["Bjorg", 12345],
4     ["Roza", 7],
5     ["Long Name Joe", 3],
6     ["Joe", 12345677889],
7 ]
8
9 for entry in data:
10     print("{} {}".format(entry[0], entry[1]))
11
12 print('-' * 16)
13
14 for entry in data:
15     print("{:<8}|{:>7}".format(entry[0], entry[1]))

```

```

1 Foo Bar 42
2 Bjorg 12345
3 Roza 7
4 Long Name Joe 3
5 Joe 12345677889
6 -----
7 Foo Bar |      42
8 Bjorg   | 12345
9 Roza    |      7
10 Long Name Joe|      3
11 Joe      |12345677889

```

Examples using format - alignment

```

1 txt = "Some text"
2
3 print("{} {}".format(txt))      # as is:  'Some text'
4 print("{:12}".format(txt))     # left:   'Some text  '
5 print("{:<12}".format(txt))    # left:   'Some text  '
6 print("{:>12}".format(txt))     # right:  '  Some text'
7 print("{:^12}".format(txt))     # center: '  Some text  '

```

Format - string

```
1 name = "Foo Bar"
2
3 print("{:s}".format(name))
4 print("{}".format(name))
```

```
1 Foo Bar
2 Foo Bar
```

Format characters and types

```
1 x = 42
2
3 print("{:b}".format(x)) # binary:    101010
4 print("{:c}".format(x)) # character: *
5 print("{:d}".format(x)) # decimal:   42      (default)
6 print("{:o}".format(x)) # octal:     52
7 print("{:x}".format(x)) # hexa:      2a
8 print("{:X}".format(x)) # hexa:      2A
9 print("{:n}".format(x)) # number:    42
10
11
12 print("{}".format(x))   # defaults to decimal
```

Format floating point number

```
1 x = 412.345678901
2
3 print("{:e}".format(x)) # exponent:    4.123457e+02
4 print("{:E}".format(x)) # Exponent:    4.123457E+02
5 print("{:f}".format(x)) # fixed point:  412.345679 (default precision is 6)
6 print("{:.2f}".format(x)) # fixed point: 412.35 (set precision to 2)
7 print("{:F}".format(x)) # same as f.    412.345679
8 print("{:g}".format(x)) # generic:      412.346   (default precision is 6)
9 print("{:G}".format(x)) # generic:      412.346
10 print("{:n}".format(x)) # number:      4412.346
11
12
13 print("{}".format(x))   # defaults to g  412.345678901
```

f-strings (formatted string literals)

Since Python 3.6

```
1 name = "Foo Bar"
2 age = 42.12
3 pi = 3.141592653589793
4 r = 2
5
6 print(f"The user {name} was born {age} years ago.")
7 print(f"The user {name:10} was born {age} years ago.")
8 print(f"The user {name:>10} was born {age} years ago.")
9 print(f"The user {name:>10} was born {age:>10} years ago.")
10
11 print(f"PI is '{pi:.3}'") # number of digits (defaults n = number)
12 print(f"PI is '{pi:.3f}'") # number of digits after decimal point
13
14 print(f"Area is {pi * r ** 2}")
15 print(f"Area is {pi * r ** 2:.3f}")
```

```
1 The user Foo Bar was born 42.12 years ago.
2 The user Foo Bar      was born 42.12 years ago.
3 The user      Foo Bar was born 42.12 years ago.
4 The user      Foo Bar was born      42.12 years ago.
5 PI is '3.14'.
6 PI is '3.142'.
7 Area is 12.566370614359172
8 Area is 12.566
```

printf using old %-syntax

This slides is here only as a historical page. It is recommended to use the **format** method!

```

1 v = 65
2 print("<%s>" % v)      # <65>
3 print("<%10s>" % v)    # <          65>
4 print("<%-10s>" % v)   # <65          >
5 print("<%c>" % v)      # <A>
6 print("<%d>" % v)      # <65>
7 print("<%0.5d>" % v)   # <00065>

```

Format braces, bracket, and parentheses

These are just some extreme special cases. Most people won't need to know about them.

To print { include {{.

To print } include }}.

```

1 print("{{{}}}".format(42))    # {42}
2
3 print("{} {} {}".format(42))  # { 42 }
4
5 print("[{}] ({}>".format(42, 42)) # [42] (42)
6
7 print("%{}".format(42))       # %42

```

Anything that is not in curly braces will be formatted as they are.

Examples using format with attributes of objects

This is also a rather strange example, I don't think I'd use it in real code.

```

1 import sys
2
3 print("{0.executable}".format(sys))
4 print("{system.argv[0]}".format(system = sys))

```

```

1 /home/gabor/venv3/bin/python
2 formatted_attributes.py

```

raw f-strings

```
1 name="foo"
2 print(r"a\nb {name}")
3 print(rf"a\nb {name}")
4 print(fr"a\nb {name}") # this is better (for vim)
```

```
1 a\nb {name}
2 a\nb foo
3 a\nb foo
```

Lists

Anything can be a lists

- Comma separated values
- In square brackets
- Can be any value, and a mix of values: Integer, Float, Boolean, None, String, List, Dictionary, ...
- But usually they are of the same type:
- Distances of astronomical objects
- Chemical Formulas
- Filenames
- Names of devices
- Objects describing attributes of a network device.
- Actions to do on your data.

```
1 stuff = [42, 3.14, True, None, "Foo Bar", ['another', 'list'], {'a': 'Dictionary', '\
2 language' : 'Python'}]
3 print(stuff)
```

```
1 [42, 3.14, True, None, 'Foo Bar', ['another', 'list'], {'a': 'Dictionary', 'language\
2 ': 'Python'}]
```

Any layout

- Layout is flexible
- Trailing comma is optional. It does not disturb us. Nor Python.

```
1 more_stuff = [  
2     42,  
3     3.14,  
4     True,  
5     None,  
6     "Foo Bar",  
7     ['another', 'list'],  
8     {  
9         'a': 'Dictionary',  
10        'language' : 'Python',  
11    },  
12 ]  
13 print(more_stuff)  
  
1 [42, 3.14, True, None, 'Foo Bar', ['another', 'list'], {'a': 'Dictionary', 'language\  
2 ': 'Python'}]
```

Lists

- Access single element: **[index]**
- Access a sublist: **[start:end]**
- Creates a copy of that sublist

```
1 planets = ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter', 'Saturn']  
2  
3 print(planets)    # ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter', 'Saturn']  
4 print(len(planets))    # 6  
5  
6 print(planets[0])    # Mercury  
7 print(type(planets[0]))    # <class 'str'>  
8 print(planets[3])    # Mars  
9  
10 print(planets[0:1])    # ['Mercury']  
11 print(type(planets[0:1]))    # <class 'list'>  
12 print(planets[0:2])    # ['Mercury', 'Venus']  
13 print(planets[1:3])    # ['Venus', 'Earth']  
14  
15 print(planets[2:])    # ['Earth', 'Mars', 'Jupiter', 'Saturn']  
16 print(planets[:3])    # ['Mercury', 'Venus', 'Earth']  
17  
18 print(planets[:])    # ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter', 'Saturn\  
19 ']
```

List slice with steps

- List slice with step: `[start:end:step]`

```
1 letters = ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j']
2
3 print(letters[:])      # ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j']
4
5 print(letters[:1])     # ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j']
6
7 print(letters[:2])     # ['a', 'c', 'e', 'g', 'i']
8
9 print(letters[1:2])    # ['b', 'd', 'f', 'h', 'j']
10
11 print(letters[2:8:2])  # ['c', 'e', 'g']
12
13 print(letters[1:20:3]) # ['b', 'e', 'h']
```

Change a List

```
1 x = ['abc', 'def', 'ghi', 'jkl']
2 x[0] = 'qqrq'
3 print(x)      # ['qqrq', 'def', 'ghi', 'jkl']
4
5 x[1:3] = ['xyz', 'dod']
6 print(x)      # ['qqrq', 'xyz', 'dod', 'jkl']
7
8
9 x[1:3] = ['bla']
10 print(x)     # ['qqrq', 'bla', 'jkl']
11
12 x[1:2] = ['elp', 'free']
13 print(x)     # ['qqrq', 'elp', 'free', 'jkl']
14
15
16 #x[1] = ['elp', 'free']
17 #print(x)    # ['qqrq', ['elp', 'free'], 'jkl']
```

- Unlike strings, lists are mutable. You can change the content of a list by assigning values to its elements.

- You can use the slice notation to change several elements at once.
- You can even have different number of elements in the slice and in the replacement. This will also change the length of the array.

Change with steps

```
1 numbers = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
2 print(numbers) # [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
3
4 numbers[1::2] = [0, 0, 0, 0, 0, 0]
5 print(numbers) # [1, 0, 3, 0, 5, 0, 7, 0, 9, 0, 11, 0]
```

List assignment and list copy

```
1 x = ['apple', 'bob', 'cat', 'drone']
2 y = x
3 x[0] = 'qqrq'
4 print(x) # ['qqrq', 'bob', 'cat', 'drone']
5 print(y) # ['qqrq', 'bob', 'cat', 'drone']
```

- There is one list in the memory and two pointers to it.
- If you really want to make a copy the pythonic way is to use the slice syntax.
- It creates a shallow copy.

```
1 x = ['apple', 'bob', 'cat', 'drone']
2 y = x[:]
3
4 x[0] = 'qqrq'
5
6 print(x) # ['qqrq', 'bob', 'cat', 'drone']
7 print(y) # ['apple', 'bob', 'cat', 'drone']
```

Deep copy

```
1 from copy import deepcopy
2
3 x = ['apple', 'bob', 'cat', 'drone']
4 y = deepcopy(x)
5
6 x[0] = 'qqrq'
7
8 print(x)      # ['qqrq', 'bob', 'cat', 'drone']
9 print(y)      # ['apple', 'bob', 'cat', 'drone']
```

join

```
1 fields = ['one', 'two and three', 'four', 'five']
2
3 together = ':'.join(fields)
4 print(together) # one:two and three:four:five
5
6 mixed = ' -=<> '.join(fields)
7 print(mixed) # one -=<> two and three -=<> four -=<> five
8
9 another = ''.join(fields)
10 print(another) # onetwo and threefourfive
```

join list of numbers

```
1 a = ["x", "2", "y"]
2 b = ["x", 2, "y"]
3 print(":".join(a))      # x:2:y
4 # print(":".join(b))    # TypeError: sequence item 1: expected string, int found
5
6 # convert elements to string using map
7 print(":".join( map(str, b) ))      # x:2:y
8
9
10 # convert elements to string using list comprehension
11 print(":".join( str(x) for x in b )) # x:2:y
```

split

- Special case: To split a string to its characters: Use the **list()** function.
- Split using more than one splitter: use **re.split**

```
1 words = "ab:cd:ef".split(':')
2 print(words)    # ['ab', 'cd', 'ef']
3
4 # special case: split by spaces
5 names = "foo  bar baz".split()
6 print(names)    # ['foo', 'bar', 'baz']
7
8 # special case: split to characters
9 chars = list("abcd")
10 print(chars)    # ['a', 'b', 'c', 'd']
```

for loop on lists

```
1 things = ['apple', 'banana', 'peach', 42]
2 for var in things:
3     print(var)
```

```
1 apple
2 banana
3 peach
4 42
```

in list

Check if the value is in the list?

```
1 words = ['apple', 'banana', 'peach', '42']
2 if 'apple' in words:
3     print('found apple')
4
5 if 'a' in words:
6     print('found a')
7 else:
8     print('NOT found a')
9
10 if 42 in words:
11     print('found 42')
12 else:
13     print('NOT found 42')
14
```

```
15 # found apple
16 # NOT found a
17 # NOT found 42
```

Where is the element in the list

```
1 words = ['cat', 'dog', 'snake', 'camel']
2 print(words.index('snake'))
3
4 print(words.index('python'))
```

```
1 2
2 Traceback (most recent call last):
3   File "examples/lists/index.py", line 6, in <module>
4     print(words.index('python'))
5 ValueError: 'python' is not in list
```

Index improved

```
1 words = ['cat', 'dog', 'snake', 'camel']
2
3 name = 'snake'
4 if name in words:
5     print(words.index(name))
6
7 name = 'python'
8 if name in words:
9     print(words.index(name))
```

•

`insert[]`.insert

```

1 words = ['apple', 'banana', 'cat']
2 print(words) # ['apple', 'banana', 'cat']
3
4 words.insert(2, 'zebra')
5 print(words) # ['apple', 'banana', 'zebra', 'cat']
6
7 words.insert(0, 'dog')
8 print(words) # ['dog', 'apple', 'banana', 'zebra', 'cat']
9
10 # Instead of this, use append (next slide)
11 words.insert(len(words), 'olifant')
12 print(words) # ['dog', 'apple', 'banana', 'zebra', 'cat', 'olifant']

```

•

`append()[].append`

```

1 names = ['Foo', 'Bar', 'Zorg', 'Bambi']
2 print(names) # ['Foo', 'Bar', 'Zorg', 'Bambi']
3
4 names.append('Qux')
5 print(names) # ['Foo', 'Bar', 'Zorg', 'Bambi', 'Qux']

```

•

`remove()[].remove`

```

1 names = ['Joe', 'Kim', 'Jane', 'Bob', 'Kim']
2 print(names) # ['Joe', 'Kim', 'Jane', 'Bob', 'Kim']
3
4 print(names.remove('Kim')) # None
5 print(names) # ['Joe', 'Jane', 'Bob', 'Kim']
6
7 print(names.remove('George'))
8 # Traceback (most recent call last):
9 #   File "examples/lists/remove.py", line 9, in <module>
10 #     print(names.remove('George')) # None
11 # ValueError: list.remove(x): x not in list

```

Remove **first** element from a list given by its value.
Throws an exception if there is no such element in the list.

-

pop]Remove element by index [].pop

```
1 planets = ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter']
2 print(planets)          # ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter']
3
4 third = planets.pop(2)
5 print(third)             # Earth
6 print(planets)          # ['Mercury', 'Venus', 'Mars', 'Jupiter']
7
8 last = planets.pop()
9 print(last)              # Jupiter
10 print(planets)          # ['Mercury', 'Venus', 'Mars']
11
12 # planets.pop(4)         # IndexError: pop index out of range
13
14 jupyter_landers = []
15 # jupyter_landers.pop()  # IndexError: pop from empty list
```

Remove and return the last element of a list. Throws an exception if the list was empty.

Remove first element of list

To remove an element by its index, use the slice syntax:

```
1 names = ['foo', 'bar', 'baz', 'moo']
2
3 first = names.pop(0)
4 print(first)      # foo
5 print(names)      # ['bar', 'baz', 'moo']
```

Remove several elements of list by index

To remove an element by its index, use the slice syntax:

```
1 names = ['foo', 'bar', 'baz', 'moo', 'qux']
2
3 names[2:4] = []
4 print(names)      # ['foo', 'bar', 'qux']
```

Use list as a queue

```
1 a_queue = []
2 print(a_queue)
3
4 a_queue.append('Moo')
5 print(a_queue)
6
7 a_queue.append('Bar')
8 print(a_queue)
9
10 first = a_queue.pop(0)
11 print(first)
12 print(a_queue)
```

```
1 []
2 ['Moo']
3 ['Moo', 'Bar']
4 Moo
5 ['Bar']
```

Queue using deque from collections

```
1  from collections import deque
2
3  # items = deque([])
4  items = deque(['foo', 'bar'])
5
6  print(type(items))  # <type 'collections.deque'>
7  print(items)        # deque(['foo', 'bar'])
8
9  items.append('zorg')
10 print(items)         # deque(['foo', 'bar', 'zorg'])
11 print(len(items))    # 3
12
13 items.append('zorg')
14 print(items)         # deque(['foo', 'bar', 'zorg', 'zorg'])
15
16 nxt = items.popleft()
17 print(nxt)           # 'foo'
18 print(items)         # deque(['bar', 'zorg', 'zorg'])
19
20 print(len(items))    # 3
21
22 if items:
23     print("The queue has items")
24 else:
25     print("The queue is empty")
```

- .append
- .popleft
- len() number of elements
- if q: to see if it has elements or if it is empty
- [deque](https://docs.python.org/3/library/collections.html#collections.deque)⁵⁹

Fixed size queue

⁵⁹<https://docs.python.org/3/library/collections.html#collections.deque>

```
1  from collections import deque
2
3  queue = deque([], maxlen = 3)
4  print(len(queue))      # 0
5  print(queue.maxlen)    # 3
6
7  queue.append("Foo")
8  queue.append("Bar")
9  queue.append("Baz")
10 print(queue)           # deque(['Foo', 'Bar', 'Baz'], maxlen=3)
11
12 queue.append("Zorg")    # Automatically removes the left-most (first) element
13 print(queue)           # deque(['Bar', 'Baz', 'Zorg'], maxlen=3)
```

List as a stack

```
1  stack = []
2
3  stack.append("Joe")
4  print(stack)
5  stack.append("Jane")
6  print(stack)
7  stack.append("Bob")
8  print(stack)
9
10 while stack:
11     name = stack.pop()
12     print(name)
13     print(stack)
```

```
1  ['Joe']
2  ['Joe', 'Jane']
3  ['Joe', 'Jane', 'Bob']
4  Bob
5  ['Joe', 'Jane']
6  Jane
7  ['Joe']
8  Joe
9  []
```

stack with deque

```
1  from collections import deque
2  stack = deque()
3
4  stack.append("Joe")
5  stack.append("Jane")
6  stack.append("Bob")
7
8  while stack:
9      name = stack.pop()
10     print(name)
11
12  # Bob
13  # Jane
14  # Joe
```

Exercies: Queue

The application should manage a queue of people.

- It will prompt the user for a new name by printing `:`, the user can type in a name and press ENTER. The app will add the name to the queue.
- If the user types in `"n"` then the application will remove the first name from the queue and print it.
- If the user types in `"x"` then the application will print the list of users who were left in the queue and it will exit.
- If the user types in `"s"` then the application will show the current number of elements in the queue.

```
1  : Foo
2  : Bar
3  : Moo
4  : n
5  next is Foo
6  : n
7  next is Bar
8  : Peter
9  : n
10 next is Moo
11 : n
12 next is Peter
13 : n
14 the queue is empty
```

Exercise: Stack

Implement a Reverse Polish Calculator

```
1  2
2  3
3  4
4  +
5  *
6  =
7  14
```

```
1  x = eXit, s = Show, [+.*/=]
2  :23
3  :19
4  :7
5  :8
6  :+
7  :3
8  :-
9  :/
10 :S
11 [23.0, -0.631578947368421]
12 :+
13 :=
14 22.36842105263158
15 :S
16 []
17 :x
```

Solution: Queue with list

```
1 queue = []
2
3 while True:
4     inp = input(":")
5     inp = inp.rstrip("\n")
6
7     if inp == 'x':
8         for name in queue:
9             print(name)
10        exit()
11
12    if inp == 's':
13        print(len(queue))
14        continue
15
16    if inp == 'n':
17        if len(queue) > 0:
18            print("next is {}".format(queue.pop(0)))
19        else:
20            print("the queue is empty")
21        continue
22
23    queue.append(inp)
```

Solution: Queue with deque

```
1 from collections import deque
2
3 queue = deque()
4
5 while True:
6     inp = input(":")
7     inp = inp.rstrip("\n")
8
9     if inp == 'x':
10        for name in queue:
11            print(name)
12        exit()
13
14    if inp == 's':
15        print(len(queue))
16        continue
```

```
17
18     if inp == 'n':
19         if len(queue) > 0:
20             print("next is {}".format(queue.popleft()))
21         else:
22             print("the queue is empty")
23         continue
24
25     queue.append(inp)
```

Solution: Reverse Polish calculator (stack) with lists

```
1  stack = []
2
3  print("x = eXit, s = Show, [+-*/=]")
4  while True:
5      val = input(':')
6
7      if val == 's':
8          print(stack)
9          continue
10
11     if val == 'x':
12         break
13
14     if val == '+':
15         a = stack.pop()
16         b = stack.pop()
17         stack.append(a+b)
18         continue
19
20     if val == '-':
21         a = stack.pop()
22         b = stack.pop()
23         stack.append(a-b)
24         continue
25
26     if val == '*':
27         a = stack.pop()
28         b = stack.pop()
29         stack.append(a*b)
30         continue
```

```
31
32     if val == '/':
33         a = stack.pop()
34         b = stack.pop()
35         stack.append(a/b)
36         continue
37
38     if val == '=':
39         print(stack.pop())
40         continue
41
42     stack.append(float(val))
```

Solution: Reverse Polish calculator (stack) with deque

```
1  from collections import deque
2
3  stack = deque()
4
5  while True:
6      val = input(':')
7
8      if val == 'x':
9          break
10
11     if val == '+':
12         a = stack.pop()
13         b = stack.pop()
14         stack.append(a+b)
15         continue
16
17     if val == '*':
18         a = stack.pop()
19         b = stack.pop()
20         stack.append(a*b)
21         continue
22
23
24     if val == '=':
25         print(stack.pop())
26         continue
27
```

```
28     stack.append(float(val))
```

Debugging Queue

The following implementation has a bug. (Even though the `n` was supposed to remove the element and the code seems to mean that it does, we still see two items after we removed the first.)

The question is how to debug this?

```
1  q = []
2
3  while True:
4      name=input("your name: ")
5
6      if name=="n":
7          print(q.pop(0))
8
9      if name=="x":
10         print(q)
11         exit()
12
13     if name=="s":
14         print(len(q))
15         exit()
16     else:
17         q.append(name)
18         continue
```

```
1  your name: Foo
2  your name: Bar
3  your name: n
4  Foo
5  your name: s
6  2
```

sort

```
1 planets = ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter', 'Saturn']
2 print(planets)      # ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter', 'Saturn']
3 planets.sort()
4 print(planets)      # ['Earth', 'Jupiter', 'Mars', 'Mercury', 'Saturn', 'Venus']
5
6 planets.sort(reverse=True)
7 print(planets)      # ['Venus', 'Saturn', 'Mercury', 'Mars', 'Jupiter', 'Earth']
```

sort numbers

```
1 numbers = [7, 2, -4, 19, 8]
2 print(numbers)      # [7, 2, -4, 19, 8]
3 numbers.sort()
4 print(numbers)      # [-4, 2, 7, 8, 19]
5
6 numbers.sort(reverse=True)
7 print(numbers)      # [19, 9, 7, 2, -4]
8
9 numbers.sort(key=abs, reverse=True)
10 print(numbers)     # [19, 9, 7, -4, 2]
```

sort mixed

```
1 mixed = [100, 'foo', 42, 'bar']
2 print(mixed)
3 mixed.sort()
4 print(mixed)
```

In Python 2 puts the numbers first in numerical order and then the strings in ASCII order.

```
1 [100, 'foo', 42, 'bar']
2 [42, 100, 'bar', 'foo']
```

In Python 3 it throws an exception.

```
1  [100, 'foo', 42, 'bar']
2  Traceback (most recent call last):
3    File "examples/lists/sort_mixed.py", line 5, in <module>
4      mixed.sort()
5  TypeError: unorderable types: str() < int()
```

key sort

- Another example to using a **key**.
- To sort the list according to length

```
1  animals = ['chicken', 'cow', 'snail', 'elephant']
2  print(animals)
3
4  animals.sort()
5  print(animals)
6
7  animals.sort(key=len)
8  print(animals)
9
10 animals.sort(key=len, reverse=True)
11 print(animals)
```

```
1  ['chicken', 'cow', 'snail', 'elephant']
2  ['chicken', 'cow', 'elephant', 'snail']
3  ['cow', 'snail', 'chicken', 'elephant']
4  ['elephant', 'chicken', 'snail', 'cow']
```

Sort tuples

Sorting tuples or list, or other complex structures

```
1 students = [  
2     ('John', 'A', 2),  
3     ('Zoro', 'C', 1),  
4     ('Dave', 'B', 3),  
5 ]  
6 print(students)  
7     # [('John', 'A', 2), ('Zoro', 'C', 1), ('Dave', 'B', 3)]  
8  
9 print(sorted(students))  
10     # [('Dave', 'B', 3), ('John', 'A', 2), ('Zoro', 'C', 1)]  
11     # sort by the first element of each tuple  
12  
13 print(sorted(students, key=lambda s : s[1]))  
14     # [('John', 'A', 2), ('Dave', 'B', 3), ('Zoro', 'C', 1)]  
15     # sort by the 2nd element of the tuples (index 1)  
16  
17 print(sorted(students, key=lambda s : s[2]))  
18     # [('Zoro', 'C', 1), ('John', 'A', 2), ('Dave', 'B', 3)]  
19     # sort by the 3rd element of the tuples (index 2)  
20  
21  
22 from operator import itemgetter  
23 print(sorted(students, key=itemgetter(2)))  
24     # [('Zoro', 'C', 1), ('John', 'A', 2), ('Dave', 'B', 3)]  
25     # maybe this is more simple than the lambda version  
26     # and probably faster
```

sort with sorted

```
1 animals = ['chicken', 'cow', 'snail', 'elephant']  
2 print(animals)           # ['chicken', 'cow', 'snail', 'elephant']  
3  
4 s = sorted(animals)  
5 print(s)                 # ['chicken', 'cow', 'elephant', 'snail']  
6 print(animals)           # ['chicken', 'cow', 'snail', 'elephant']  
7  
8 r = sorted(animals, reverse=True, key=len)  
9 print(r)                 # ['elephant', 'chicken', 'snail', 'cow']  
10 print(animals)           # ['chicken', 'cow', 'snail', 'elephant']
```

sort vs. sorted

The `sort()` method will sort a list in-place and return `None`.

The built-in `sorted()` function will return the sorted list and leave the original list intact.

key sort with sorted

To sort the list according to length using `sorted`

```
1 animals = ['snail', 'cow', 'elephant', 'chicken']
2 animals_in_abc = sorted(animals)
3
4 print(animals)
5 print(animals_in_abc)
6
7 animals_by_length = sorted(animals, key=len)
8 print(animals_by_length)
```

```
1 ['snail', 'cow', 'elephant', 'chicken']
2 ['chicken', 'cow', 'elephant', 'snail']
3 ['cow', 'snail', 'chicken', 'elephant']
```

Sorting characters of a string

```
1 letters = 'axzb'
2 print(letters)          # 'axzb'
3 s = sorted(letters)
4 print(s)                # ['a', 'b', 'x', 'z']
5 print(letters)          # 'axzb'
6
7 r = ''.join(sorted(letters))
8 print(r)                # abxz
```

range

```
1  for i in range(11, 18, 2):
2      print(i)
3  # 11
4  # 13
5  # 15
6  # 17
7
8  for i in range(5, 7):
9      print(i)
10 # 5
11 # 6
12
13 for i in range(3):
14     print(i)
15 # 0
16 # 1
17 # 2
```

Looping over index

```
1  things = ['abc', 'def', 'ghi', 42]
2  for var in things:
3      print(var)
```

```
1  things = ['abc', 'def', 'ghi', 42]
2  for i in range(len(things)):
3      print(i, things[i])
4
5  # 0 abc
6  # 1 def
7  # 2 ghi
8  # 3 42
```

Enumerate lists

```
1 planets = ['Mercury', 'Venus', 'Earth', 'Mars', 'Jupiter', 'Saturn']
2 for idx, planet in enumerate(planets):
3     print(idx, planet)
4
5 print('')
6 enu = enumerate(planets)
7 print(enu.__class__.__name__)
8 print(enu)
```

```
1 0 Mercury
2 1 Venus
3 2 Earth
4 3 Mars
5 4 Jupiter
6 5 Saturn
7
8 enumerate
9 <enumerate object at 0x7f2c2402adc8>
```

List operators

```
1 a = ['one', 'two']
2 b = ['three']
3
4 print(a)      # ['one', 'two']
5 print(a * 2)  # ['one', 'two', 'one', 'two']
6 print(a + b)  # ['one', 'two', 'three']
```

List of lists

```
1 x = ['abc', 'def']
2 print(x)      # ['abc', 'def']
3
4 y = [x, 'xyz']
5 print(y)      # [['abc', 'def'], 'xyz']
6 print(y[0])   # ['abc', 'def']
7
8 print(x[0])   # abc
9 print(y[0][0]) # abc
```

List assignment

List assignment works in “parallel” in Python.

```
1 x, y = 1, 2
2 print(x)      # 1
3 print(y)      # 2
4
5 x, y = y, x
6 print(x)      # 2
7 print(y)      # 1
```

```
1 x,y = f()  # works if f returns a list of 2 elements
```

It will throw a run-time `ValueError` exception if the number of values in the returned list is not 2. (Both for fewer and for more return values).

List documentation

- [datastructures](http://docs.python.org/tutorial/datastructures.html)⁶⁰

tuple

Tuple

- A tuple is a fixed-length immutable list. It cannot change its size or content.
- A tuple is denoted with parentheses: (1,2,3)

⁶⁰<http://docs.python.org/tutorial/datastructures.html>

```

1 t = ('a', 'b', 'c')
2 print(t)    # ('a', 'b', 'c')

```

List

- Elements of a list can be changed via their index or via the list slice notation.
- A list can grow and shrink using **append** and **pop** methods or using the **slice** notation.
- A list is denoted with square brackets: [1, 2, 3]

```

1 l = ['abc', 'def', 'qqrq']
2 t = tuple(l)
3 print(l) # ['abc', 'def', 'qqrq']
4 print(t) # ('abc', 'def', 'qqrq')

```

Tuples are rarely used. There are certain places where Python or some module require tuple (instead of list) or return a tuple (instead of a list) and in each place it will be explained. Otherwise you don't need to use tuples.

e.g. keys of dictionaries can be tuple (but not lists).

Exercise: color selector menu

- In a script have a list of colors. Write a script that will display a menu (a list of numbers and the corresponding color) and prompts the user for a number. The user needs to type in one of the numbers. That's the selected color.

1. blue
2. green
3. yellow
4. white

- For extra credit make sure the system is user-proof and it won't blow up on various incorrect input values. (e.g Floating point number. Number that is out of range, non-number)
- For more credit allow the user to supply the number of the color on the command line. **python color.py 3**. If that is available, don't prompt.
- For further credit allow the user to provide the name of the color on the command line: **python color.py yellow** Can you handle color names that are not in the expected case (e.g. YelloW)?
- Any more ideas for improvement?

Exercise: count digits

Given a list of numbers `numbers = [1203, 1256, 312456, 98]`, count how many times each digit appears? The output will look like this:

```
1 0 1
2 1 3
3 2 3
4 3 2
5 4 1
6 5 2
7 6 2
8 7 0
9 8 1
10 9 1
```

Exercise: Create list

Given a list of strings with words separated by spaces, create a single list of all the words.

```
1 lines = [
2     'grape banana mango',
3     'nut orange peach',
4     'apple nut banana apple mango',
5 ]
6
7 fruits = ['grape', 'banana', 'mango', 'nut', 'orange', 'peach', 'apple', 'nut', 'ban\
8 ana', 'apple', 'mango']
```

Then create a list of unique values sorted by abc.

```
1 unique_fruites = ['apple', 'banana', 'grape', 'mango', 'nut', 'orange', 'peach']
```

Exercise: Count words

```
1 celestial_objects = [
2     'Moon', 'Gas', 'Asteroid', 'Dwarf', 'Asteroid', 'Moon', 'Asteroid'
3 ]
```

Expected output:

```
1 Moon      2
2 Gas       1
3 Asteroid  3
4 Dwarf     1
```

Exercise: Check if number is prime

Write a program that gets a number on the command line and prints “True” if the number is a prime number or “False” if it isn’t.

```
1 python is_prime.py 42
2 False
3 python is_prime.py 19
4 True
```

Exercise: DNA sequencing

- A, C, T, G are called bases or nucleotides
- Given a sequence like ‘ACCGXXCXXGTTACTGGGCXTTGT’ (nucleotides mixed up with other elements) return the sequences containing only ACTG ordered by length.
- The above string can be split up to [‘ACCG’, ‘C’, ‘GTTACTGGGC’, ‘TTGT’] and then it can be sorted to get the following:
- Expected result: [‘GTTACTGGGC’, ‘ACCG’, ‘TTGT’, ‘C’]

Solution: menu

```
1 colors = ['blue', 'yellow', 'black', 'purple']
2 for ix in range(len(colors)):
3     print("{} {} ".format(ix+1, colors[ix]))
4
5 selection = input("Select color: ")
6 if not selection.isdecimal():
7     exit(f"We need a number between 1 and {len(colors)}")
8
9 if int(selection) < 1 or int(selection) > len(colors):
10     exit(f"The number must be between 1 and {len(colors)}")
11
12 col = int(selection) - 1
13 print(colors[col])
```

- We would like to show a menu where each number corresponds to one element of the list so this is one of the places where we need to iterate over the indexes of a list.
- `len(colors)` gives us the length of the list (in our case 4)
- `range(len(colors))` is the range of numbers between 0 and 4 (in our case), meaning 0, 1, 2, 3.
- (Sometimes people explicitly write 4 in this solution, but if later we change the list and include another color we'll have to remember updating this number as well. This is error prone and it is very easy to deduct this number from the data we already have. (The list.))
- We start the list from 0, but when we display the menu we would like to show the numbers 1-4 to make it more human friendly. Therefore we show `ix+1` and the color from locations `ix`.
- We ask for input and save it in a variable.
- We use the `isdecimal` method to check if the user typed in a decimal number. We give an error and exit if not.
- Then we check if the users provided a number in the correct range of values. We give an error and exit if not.
- then we convert the value to the correct range of numbers (remember, the user sees and selects numbers between 1-4 and we need them between 0-3).

Solution: count digits

```

1 numbers = [1203, 1256, 312456, 98]
2
3 count = [0] * 10 # same as [0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
4
5 for num in numbers:
6     for char in str(num):
7         count[int(char)] += 1
8
9 for d in range(0, 10):
10    print("{} {}".format(d, count[d]))

```

First we have to decide where are we going to store the counts. A 10 element long list seems to fit our requirements so if we have 3 0s and 2 8s we would have `[3, 0, 0, 0, 0, 0, 0, 0, 2, 0]`.

- We have a list of numbers.
- We need a place to store the counters. For this we create a variable called counter which is a list of 10 0s. We are going to count the number of times the digit 3 appears in `counters[3]`.
- We iterate over the numbers so `num` is the current number. (e.g. 1203)
- We would like to iterate over the digits in the current number now, but if we write `for var in num` we will get an error `TypeError: 'int' object is not iterable` because `num` is a number, but numbers are not iterables, so we cannot iterate over them. So we need to convert it to a string using `str`.

- On each iteration char will be one character (which in or case we assume that will be a digit, but still stored as a string).
 - `int(char)` will convert the string to a number so for example “2” will be converted to 2.
 - `count[int(char)]` is going to be `char[2]` if char is “2”. That’s the location in the list where we count how many times the digit 2 appears in our numbers.
 - We increment it by one as we have just encountered a new copy of the given digit.
 - That finished the data collection.
-
- The second for-loop iterates over all the “possible digits” that is from 0-9, prints out the digit and the counter in the respective place.

Solution: Create list

```
1 lines = [  
2     'grape banana mango',  
3     'nut orange peach',  
4     'apple nut banana apple mango',  
5 ]  
6  
7 one_line = ' '.join(lines)  
8 print(one_line)  
9 fruits = one_line.split()  
10 print(fruits)  
11  
12 unique_fruits = []  
13 for word in fruits:  
14     if word not in unique_fruits:  
15         unique_fruits.append(word)  
16 print(sorted(unique_fruits))  
17  
18  
19 # a simpler way using a set, but we have not learned sets yet.  
20 unique = sorted(set(fruits))  
21 print(unique)
```

Solution: Count words

```
1 celestial_objects = [  
2     'Moon', 'Gas', 'Asteroid', 'Dwarf', 'Asteroid', 'Moon', 'Asteroid'  
3 ]  
4  
5 names = []  
6 counter = []  
7  
8 for name in celestial_objects:  
9     if name in names:  
10         idx = names.index(name)  
11         counter[idx] += 1  
12     else:  
13         names.append(name)  
14         counter.append(1)  
15  
16 for i in range(len(names)):  
17     print("{:12} {}".format(names[i], counter[i]))
```

Solution: Check if number is prime

```
1 import sys  
2  
3 n = int(sys.argv[1])  
4  
5 #print(n)  
6  
7 is_prime = True  
8 for i in range(2, int( n ** 0.5) + 1):  
9     if n % i == 0:  
10         is_prime = False  
11         break  
12  
13 print(is_prime)  
14  
15  
16 # math.sqrt(n) might be clearer than n ** 0.5
```

Solution: DNA sequencing

```

1 dna = 'ACCGXXCXXGTTACTGGGCXTTGT'
2 sequences = dna.split('X')
3 sequences.sort(key=len, reverse=True)
4
5 new_seq = []
6 for w in sequences:
7     if len(w) > 0:
8         new_seq.append(w)
9
10 print(sequences)
11 print(new_seq)

```

Solution: DNA sequencing with filter

```

1 dna = 'ACCGXXCXXGTTACTGGGCXTTGT'
2 sequences = dna.split('X')
3 sequences.sort(key=len, reverse=True)
4
5 def not_empty(x):
6     return len(x) > 0
7
8 print(sequences)
9 sequences = list( filter(not_empty, sequences) )
10 print(sequences)

```

Solution: DNA sequencing with filter and lambda

```

1 dna = 'ACCGXXCXXGTTACTGGGCXTTGT'
2 sequences = dna.split('X')
3 sequences.sort(key=len, reverse=True)
4
5 print(sequences)
6 sequences = list( filter(lambda x: len(x) > 0, sequences) )
7 print(sequences)

```

•

```
extend][].extend
```

```
1 names = ['Foo Bar', 'Orgo Morgo']
2
3 names.extend(['Joe Doe', 'Jane Doe'])
4 print(names) # ['Foo Bar', 'Orgo Morgo', 'Joe Doe', 'Jane Doe']
```

append vs. extend

What is the difference between [].append and [].extend ?

The method **append** adds its parameter as a single element to the list, while **extend** gets a list and adds its content.

```
1 names = ['Foo Bar', 'Orgo Morgo']
2 more = ['Joe Doe', 'Jane Doe']
3 names.extend(more)
4 print(names) # ['Foo Bar', 'Orgo Morgo', 'Joe Doe', 'Jane Doe']
5
6 names = ['Foo Bar', 'Orgo Morgo']
7 names.append(more)
8 print(names) # ['Foo Bar', 'Orgo Morgo', ['Joe Doe', 'Jane Doe']]
9
10 names = ['Foo', 'Bar']
11 names.append('Qux')
12 print(names) # ['Foo', 'Bar', 'Qux']
13
14 names = ['Foo', 'Bar']
15 names.extend('Qux')
16 print(names) # ['Foo', 'Bar', 'Q', 'u', 'x']
```

split and extend

When collecting data which is received from a string via splitting, we would like to add the new elements to the existing list:

```
1 lines = [  
2     'abc def ghi',  
3     'hello world',  
4 ]  
5  
6 collector = []  
7  
8 for l in lines:  
9     collector.extend(l.split())  
10    print(collector)  
11  
12 # ['abc', 'def', 'ghi']  
13 # ['abc', 'def', 'ghi', 'hello', 'world']
```

Files

Open and read file

```
1 filename = 'examples/files/numbers.txt'
2
3 with open(filename, 'r') as fh:
4     for line in fh:
5         print(line)          # duplicate newlines
6
7 # close is called when we leave the 'with'
```

Filename on the command line

```
1 import sys
2
3 def main():
4     if len(sys.argv) != 2:
5         exit("Usage: " + sys.argv[0] + " FILENAME")
6     filename = sys.argv[1]
7     with open(filename) as fh:
8         print("Working on the file", filename)
9
10 main()
```

```
1 $ python single.py
2 Usage: single.py FILENAME
3
4 $ python single.py numbers.txt
5 Working on the file numbers.txt
```

Filehandle with and without

```
1 filename = 'examples/files/numbers.txt'
2
3 fh = open(filename, 'r')
4 print(fh)      # <open file 'numbers.txt', mode 'r' at 0x107084390>
5 data = fh.read()
6 # do something with the data
7 fh.close()
8 print(fh)      # <closed file 'numbers.txt', mode 'r' at 0x107084390>
9
10
11
12 with open(filename, 'r') as fh:
13     print(fh)  # <open file 'numbers.txt', mode 'r' at 0x1070840c0>
14     data = fh.read()
15 print(fh)      # <closed file 'numbers.txt', mode 'r' at 0x1070840c0>
```

Filehandle with return

```
1 import sys
2
3 def process_file(filename):
4     with open(filename, 'r') as fh:
5
6         for line in fh:
7             line = line.rstrip("\n")
8             if len(line) > 0:
9                 if line[0] == '#':
10                     return
11 # some comment
12
13             if len(line) > 1:
14                 if line[0:2] == '//':
15                     return
16
17             print(line)
18
19
20 process_file(sys.argv[0])
```

Read file remove newlines

```
1 filename = 'examples/files/numbers.txt'
2
3 with open(filename, 'r') as fh:
4     for line in fh:
5         line = line.rstrip("\n")
6         print(line)
```

Read all the lines into a list

```
1 filename = 'examples/files/numbers.txt'
2
3 with open(filename, 'r') as fh:
4     lines_list = fh.readlines() # reads all the lines into a list
5
6 # print number of lines
7 print(len(lines_list))
8
9 for line in lines_list:
10     print(line, end="")
```

Read all the characters into a string (slurp)

```
1 filename = 'examples/files/numbers.txt'
2
3 with open(filename, 'r') as fh:
4     lines_str = fh.read() # reads all the lines into a string
5
6 print(len(lines_str)) # number of characters in file
7
8 print(lines_str) # the content of the file
```

`read(20)` will read 20 bytes.

Not existing file

```
1 filename = 'examples/files/unicorns.txt'
2
3 with open(filename, 'r') as fh:
4     lines = fh.read()
5 print("still running")
6
7 # Traceback (most recent call last):
8 #   File "examples/files/open_file.py", line 5, in <module>
9 #     with open(filename, 'r') as fh:
10 # IOError: [Errno 2] No such file or directory: 'examples/files/unicorns.txt'
```

Open file exception handling

Exception handling

```
1 filename = 'examples/files/unicorns.txt'
2
3 try:
4     with open(filename, 'r') as fh:
5         lines = fh.read()
6 except Exception as err:
7     print('There was some error in the file operations.')
8     print(err)
9     print(type(err).__name__)
10
11 print('Still running.')
```

Open many files - exception handling

```
1 import sys
2
3
4 def main():
5     for filename in sys.argv[1:]:
6         try:
7             #do_some_stuff(filename)
8             with open(filename) as fh:
9                 total = 0
10                count = 0
11                for line in fh:
12                    number = float(line)
```

```
13         total += number
14         count += 1
15         print("Average: ", total/count)
16     except Exception:
17         print("trouble with {}".format(filename))
18
19 main()
```

```
1 23
2 1
3 192
4 17
```

```
1
```

```
1 python average_from_files.pyt number_per_line.txt empty.txt number_per_line2.txt
```

```
1 Average: 58.25
2 trouble with empty.txt
3 Average: 3.5
```

Writing to file

```
1 filename = 'data.txt'
2
3 with open(filename, 'w') as out:
4     out.write('text\n')
```

Append to file

```
1 filename = 'data.txt'
2
3 with open(filename, 'a') as out:
4     out.write('append more text\n')
```

Binary mode

```
1 filename = 'README'
2
3 try:
4     with open(filename, 'rb') as fh:
5         while True:
6             binary_str = fh.read(5000)
7             print(len(binary_str))
8             if len(binary_str) == 0:
9                 break
10            # do something with the content of the binary_str
11 except Exception:
12     pass
13
14 # 5000
15 # 5000
16 # 5000
17 # 1599
18 # 0
```

Does file exist? Is it a file?

- [os.path.exists](#)⁶¹
- [os.path.isfile](#)⁶²
- [os.path.isdir](#)⁶³

Exercise: count numbers

```
1 23 345 12345
2 67 189 23 17
```

1. Given the file **examples/files/numbers.txt** (or a similar file), count how many times each digit appears? The output will look like this. Just different values.
2. Save the results in a file called **report.txt**.

⁶¹<https://docs.python.org/library/os.path.html#os.path.exists>

⁶²<https://docs.python.org/library/os.path.html#os.path.isfile>

⁶³<https://docs.python.org/library/os.path.html#os.path.isdir>

```
1 0 0
2 1 3
3 2 3
4 3 4
5 4 2
6 5 2
7 6 1
8 7 2
9 8 1
10 9 1
```

Exercise: strip newlines

How to read all the lines of a file into a list and remove trailing newlines?

Exercise: color selector

Create a file similar to the colors.txt file and use it as the list of colors in the earlier example where we prompted for a color.

```
1 blue
2 yellow
3 white
4 green
```

Extend the previous example by letting the user provide the name of the file on the command line:
`python color.py examples/files/color.txt`

Exercise: ROT13

Implement [ROT13](https://en.wikipedia.org/wiki/ROT13)⁶⁴:

- Create a function that given a string return the rot13 of it.
- Create a script that given a file it will replace with the rot13 of it.

How to check if it works properly:

⁶⁴<https://en.wikipedia.org/wiki/ROT13>

```
1 txt = "any text"
2 encrypted = rot13(txt)
3 decrypted = rot13(encrypted)
4 assert decrypted == text
```

Exercise: Combine lists

```
1 Tomato=78
2 Avocado=23
3 Pumpkin=100
```

```
1 Cucumber=17
2 Avocado=10
3 Cucumber=10
```

Write a script that takes the two files and combines them adding the values for each vegetable. The expected result is:

```
1 Avocado=33
2 Cucumber=27
3 Pumpkin=100
4 Tomato=78
```

Solution: count numbers

```
1 import sys
2
3 if len(sys.argv) < 2:
4     exit("Need name of file.")
5
6 counter = [0] * 10
7 filename = sys.argv[1]
8 with open(filename) as fh:
9     for line in fh:
10         for c in line.rstrip("\n"):
11             if c == ' ':
12                 continue
13
14             c = int(c)
15             counter[c] += 1
```

```
16
17 for i in range(10):
18     print("{} {}".format(i, counter[i]))
```

Solution: strip newlines

```
1 import sys
2 filename = sys.argv[0]
3 with open(filename) as fh:
4     lines = []
5     for line in fh:
6         lines.append(line.rstrip("\n"))
7     print(lines)
```

Solution: color selector

```
1 def main():
2     try:
3         with open('colors.txt') as fh:
4             colors = []
5             for line in fh:
6                 colors.append(line.rstrip("\n"))
7     except IOError:
8         print("Could not open colors.txt")
9         exit()
10
11     for i in range(len(colors)):
12         print("{} {}".format(i, colors[i]))
13
14     c = int(input("Select color: "))
15     print(colors[c])
16
17 main()
```

Solution: Combine lists

```
1  a_names = []
2  a_values = []
3  with open('examples/files/a.txt') as fh:
4      for line in fh:
5          k, v = line.rstrip("\n").split("=")
6          a_names.append(k)
7          a_values.append(int(v))
8
9  b_names = []
10 b_values = []
11 with open('examples/files/b.txt') as fh:
12     for line in fh:
13         k, v = line.rstrip("\n").split("=")
14         b_names.append(k)
15         b_values.append(int(v))
16
17 c_names = []
18 c_values = []
19
20 for i in range(len(a_names)):
21     if a_names[i] in c_names:
22         j = c_names.index(a_names[i])
23         c_values[j] += a_values[i]
24     else:
25         c_names.append( a_names[i] )
26         c_values.append( a_values[i] )
27
28 for i in range(len(b_names)):
29     if b_names[i] in c_names:
30         j = c_names.index(b_names[i])
31         c_values[j] += b_values[i]
32     else:
33         c_names.append( b_names[i] )
34         c_values.append( b_values[i] )
35
36
37 with open('out.txt', 'w') as fh:
38     for i in range(len(c_names)):
39         fh.write("{}={}\n".format(c_names[i], c_values[i]))
```

Read text file

```
1 filename = 'examples/files/numbers.txt'
2
3 with open(filename, 'r') as fh:    # open(filename) would be enough
4     for line in fh:
5         print(line)                # duplicate newlines
6         #print(line, end="")      # eliminte the trailing newline of print
```

Open and read file

In some code you will encounter the following way of opening files. This was used before “with” was added to the language. It is not a recommended way of opening a file as you might easily forget to call “close” and that might cause trouble. For example you might loose data. Don’t do that.

```
1 filename = 'examples/files/numbers.txt'
2
3 fh = open(filename, 'r')
4 for line in fh:
5     print(line)                # duplicate newlines
6 fh.close()
```

Direct access of a line in a file

```
1 names = ['Foo', 'Bar', 'Baz']
2 for name in names:
3     print(name)
4 print(names[1])
5
6
7 filename = 'data/README'
8 with open(filename, 'r') as fh:
9     for line in fh:
10         print(line)
11
12 with open(filename, 'r') as fh:
13     print(fh[2])
```

```
1  Traceback (most recent call last):
2    File "examples/files/fh_access.py", line 14, in <module>
3      print(fh[2])
4  TypeError: '_io.TextIOWrapper' object is not subscriptable
```

This does NOT work because files can only be accessed sequentially.

Example

```
1  begin test
2  do something
3  report
4  total: 42
5  more things
6  more
7  another total: 100
8  more data
```

```
1  import sys
2  import os
3
4  #print(sys.argv)
5  if len(sys.argv) < 2:
6      #exit()
7      exit(f"Usage: {sys.argv[0]} FILENAME")
8
9  # print(sys.argv[0])
10 # print(sys.argv[1])
11
12 #filename = 'sample.txt'
13
14 #filename = input("type in filename: ")
15
16 filename = sys.argv[1]
17
18 #if not os.path.exists(filename):
19 #    exit(f"File {filename} does not exist")
20
```

```
21 with open(filename, 'r') as fh:
22     for line in fh:
23         line = line.rstrip("\n")
24         print(line)
25         #if "total" in line:
26         #     print(line)
27
```

Dictionary (hash)

What is a dictionary

- Unordered key-value pairs.
- Keys are immutables (numbers, strings, tuples).
- Values can be any object.

When to use dictionaries

- ID to Name mapping.
- Object to Count mapping.
- Name of a feature to value of the feature.
- Name of an attribute to value of the attribute.

Dictionary

```
1 user = {}
2 user['name'] = 'Foobar'
3 print(user)          # {'name': 'Foobar'}
4
5 user['email'] = 'foo@bar.com'
6 print(user)          # {'name': 'Foobar', 'email': 'foo@bar.com'}
7
8 the_name = user['name']
9 print(the_name)      # Foobar
10
11 field = 'name'
12 the_value = user[field]
13 print(the_value)     # Foobar
14
15 user['name'] = 'Edith Piaf'
16 print(user)          # {'name': 'Edith Piaf', 'email': 'foo@bar.com'}
```

keys

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 print(user)    # {'lname': 'Bar', 'fname': 'Foo'}
7
8 print(user.keys())    # ['lname', 'fname']
```

- Keys are returned in seemingly random order.

Loop over keys

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 for k in user.keys():
7     print(k)
8
9 # lname
10 # fname
11
12 for k in user.keys():
13     print("{} -> {}".format(k, user[k]))
14
15 # lname -> Bar
16 # fname -> Foo
```

Loop using items

```
1 people = {
2     "foo" : "123",
3     "bar" : "456",
4     "qux" : "789",
5 }
6
7 for name, uid in people.items():
8     print("{} => {}".format(name, uid))
```

```
1 foo => 123
2 bar => 456
3 qux => 789
```

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 for t in user.items():      # returns tuples
7     print("{} -> {}".format(t[0], t[1]))
8     #print("{} -> {}".format(*t))
9
10 # lname -> Bar
11 # fname -> Foo
```

values

- Values are returned in the same random order as the keys are.

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 print(user)    # {'lname': 'Bar', 'fname': 'Foo'}
7
8 print(user.keys())    # ['lname', 'fname']
9
10 print(user.values())  # ['Bar', 'Foo']
```

Not existing key

If we try to fetch the value of a key that does not exist, we get an exception.

```
1 def main():
2     user = {
3         'fname': 'Foo',
4         'lname': 'Bar',
5     }
6
7     print(user['fname'])
8     print(user['email'])
9
10 main()
```

```
1 Foo
2 Traceback (most recent call last):
3   File "examples/dictionary/no_such_key.py", line 11, in <module>
4     main()
5   File "examples/dictionary/no_such_key.py", line 9, in main
6     print(user['email'])
7   KeyError: 'email'
```

Get key

If we use the `get` method, we get `None` if the key does not exist.

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4     'address': None,
5 }
6
7 print(user.get('fname'))
8 print(user.get('address'))
9 print(user.get('email'))
10
11 print(user.get('answer', 42))
```

```
1 Foo
2 None
3 None
4 42
```

None will be interpreted as False, if checked as a boolean.

Does the key exist?

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 print('fname' in user) # True
7 print('email' in user) # False
8 print('Foo' in user)   # False
9
10 for k in ['fname', 'email', 'lname']:
11     if k in user:
12         print("{} => {}".format(k, user[k]))
13
14 # fname => Foo
15 # lname => Bar
```

```
1 True
2 False
3 False
4 fname => Foo
5 lname => Bar
```

Does the value exist?

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 print('fname' in user.values()) # False
7 print('Foo' in user.values())  # True
```

```
1 False
2 True
```

Delete key

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4     'email': 'foo@bar.com',
5 }
6
7 print(user) # {'lname': 'Bar', 'email': 'foo@bar.com', 'fname': 'Foo'}
8
9 fname = user['fname']
10 del user['fname']
11 print(fname) # Foo
12 print(user) # {'lname': 'Bar', 'email': 'foo@bar.com'}
13
14 lname_was = user.pop('lname')
15 print(lname_was) # Bar
16 print(user) # {'email': 'foo@bar.com'}
```

```
1 {'fname': 'Foo', 'lname': 'Bar', 'email': 'foo@bar.com'}
2 Foo
3 {'lname': 'Bar', 'email': 'foo@bar.com'}
4 Bar
5 {'email': 'foo@bar.com'}
```

List of dictionaries

```

1  people = [
2      {
3          'name' : 'Foo Bar',
4          'email' : 'foo@example.com'
5      },
6      {
7          'name' : 'Qux Bar',
8          'email' : 'qux@example.com',
9          'address' : 'Borg, Country',
10         'children' : [
11             'Alpha',
12             'Beta'
13         ]
14     }
15 ]
16
17 print(people)
18 print(people[0]['name'])
19 print(people[1]['children'][0])
20
21 print(list(map(lambda p: p['name'], people)))

```

```

1  [{'name': 'Foo Bar', 'email': 'foo@example.com'}, {'name': 'Qux Bar', 'email': 'qux@\\
2  example.com', 'address': 'Borg, Country', 'children': ['Alpha', 'Beta']}]
3  Foo Bar
4  Alpha
5  ['Foo Bar', 'Qux Bar']

```

Shared dictionary

```

1  people = [
2      {
3          "name" : "Foo",
4          "id" : "1",
5      },
6      {
7          "name" : "Bar",
8          "id" : "2",
9      },
10     {
11         "name" : "Moo",

```

```

12         "id"    : "3",
13     },
14 ]
15
16 by_name = {}
17 by_id = {}
18 for p in people:
19     by_name[ p['name' ] ] = p
20     by_id[ p['id' ] ] = p

```

Insertion Order is kept

Since Python 3.7

```
1 d = {}
2 d['a'] = 1
3 d['b'] = 2
4 d['c'] = 3
5 d['d'] = 4
6 print(d)
```

```
1 {'a': 1, 'b': 2, 'c': 3, 'd': 4}
```

Change order of keys in dictionary - OrderedDict

```
1 from collections import OrderedDict
2
3 d = OrderedDict()
4 d['a'] = 1
5 d['b'] = 2
6 d['c'] = 3
7 d['d'] = 4
8
9 print(d)
10 d.move_to_end('a')
11
12 print(d)
13 d.move_to_end('d', last=False)
14
15 print(d)
16
17 for key in d.keys():
18     print(key)
```

```
1 OrderedDict([('a', 1), ('b', 2), ('c', 3), ('d', 4)])
2 OrderedDict([('b', 2), ('c', 3), ('d', 4), ('a', 1)])
3 OrderedDict([('d', 4), ('b', 2), ('c', 3), ('a', 1)])
4 d
5 b
6 c
7 a
```

Set order of keys in dictionary - OrderedDict

```

1  from collections import OrderedDict
2
3  d = {}
4  d['a'] = 1
5  d['b'] = 2
6  d['c'] = 3
7  d['d'] = 4
8  print(d)
9
10 planned_order = ('b', 'c', 'd', 'a')
11 e = OrderedDict(sorted(d.items(), key=lambda x: planned_order.index(x[0])))
12 print(e)
13
14 print('-----')
15 # Create index to value mapping dictionary from a list of values
16 planned_order = ('b', 'c', 'd', 'a')
17 plan = dict(zip(planned_order, range(len(planned_order))))
18 print(plan)
19
20 f = OrderedDict(sorted(d.items(), key=lambda x: plan[x[0]]))
21 print(f)

1  {'a': 1, 'b': 2, 'c': 3, 'd': 4}
2  OrderedDict([('b', 2), ('c', 3), ('d', 4), ('a', 1)])
3  -----
4  {'b': 0, 'c': 1, 'd': 2, 'a': 3}
5  OrderedDict([('b', 2), ('c', 3), ('d', 4), ('a', 1)])

```

Exercise: count characters

Given a long text, count how many times each character appears?

```

1  text = """
2  This is a very long text.
3  OK, maybe it is not that long after all.
4  """

```

Extra credit: Change the code so it will be able to count characters of a file.

Exercise: count words

Part of the code:

```
1 words = ['Wombat', 'Rhino', 'Sloth', 'Tarantula', 'Sloth', 'Rhino', 'Sloth']
```

Expected output: (the order is not important)

```
1 Wombat:1
2 Rhino:2
3 Sloth:3
4 Tarantula:1
```

Exercise: count words from a file

Given a file with words and spaces and newlines only, count how many times each word appears.

```
1 Lorem ipsum dolor qui ad labor ad labor sint dolor tempor incididunt ut labor ad do\
2 lore lorem ad
3 Ut labor ad dolor lorem qui ad ut labor ut ad commodo commodo
4 Lorem ad dolor in reprehenderit in lorem ut labor ad dolore eu in labor dolor
5 sint occaecat ad labor proident sint in in qui labor ad dolor ad in ad labor
```

- Based on [Lorem Ipsum](https://www.lipsum.com/)⁶⁵

Expected result for the above file:

1	ad	13
2	commodo	2
3	dolor	6
4	dolore	2
5	eu	1
6	in	6
7	incidunt	1
8	ipsum	1
9	labor	10
10	lorem	5
11	occaecat	1
12	proident	1
13	qui	3
14	reprehenderit	1
15	sint	3
16	tempor	1
17	ut	5

Exercise: Apache log

Every web server logs the visitors and their requests in a log file. The Apache web server has a log file similar to the following file. (Though I have trimmed the lines for the exercise.) Each line is a “hit”, a request from the browser of a visitor.

Each line starts with the IP address of the visitor. e.g. 217.0.22.3.

Given such a log file from Apache, report how many hits (line were from each IP address.

```

1 127.0.0.1 - - [10/Apr/2007:10:39:11] "GET / HTTP/1.1" 500 606 "-"

3 217.0.22.3     7

```

Exercise: Combine lists again

See the same exercise in the previous chapter.

Exercise: counting DNA bases

Given a sequence like this: “ACTNGTGCTYGATRGTAGCYXGTN”, print out the distribution of the elements to get the following result:

```
1 A 3 - 12.50 %
2 C 3 - 12.50 %
3 G 6 - 25.00 %
4 N 2 - 8.33 %
5 R 1 - 4.17 %
6 T 6 - 25.00 %
7 X 1 - 4.17 %
8 Y 2 - 8.33 %
```

Exercise: Count Amino Acids

- Each sequence consists of many repetition of the 4 bases represented by the ACTG characters.
- There are 64 codons (sets of 3 bases following each other)
- There are 22 [Amino Acids](https://en.wikipedia.org/wiki/Amino_acid)⁶⁶ each of them are represented by 3 bases.
- Some of the Amino Acids can be represented in multiple ways. For example Histidine can be encoded by both CAU, CAC)
- We have a DNA sequence
- Count the Amino acids from the sequence. (For our purposes feel free to generate a DNA sequence with a random number generator.

Exercise: List of dictionaries

Given the following file build a list of dictionaries where each dictionary represents one person. The keys in the dictionary are the names of the columns (fname, lname, born) the values are the respective values from each row.

⁶⁶https://en.wikipedia.org/wiki/Amino_acid

```
1  fname,lname,born
2  Graham,Chapman,8 January 1941
3  Eric,Idle,29 March 1943
4  Terry,Gilliam,22 November 1940
5  Terry,Jones,1 February 1942
6  John,Cleese,27 October 1939
7  Michael,Palin,5 May 1943

1  print(people[1]['fname']) # Eric
```

Exercise: Dictinoary of dictionaries

Given the following file build a dictionary of dictionaries where each internal dictionary represents one person.

The keys in the internal dictionaries are the names of the columns (fname, lname, born) the values are the respective values from each row.

In the outer dictinary the keys are the (fname, lname) tuples.

```
1  fname,lname,born
2  Graham,Chapman,8 January 1941
3  Eric,Idle,29 March 1943
4  Terry,Gilliam,22 November 1940
5  Terry,Jones,1 February 1942
6  John,Cleese,27 October 1939
7  Michael,Palin,5 May 1943

1  print(people[('Eric', 'Idle')]['born']) # 29 March 1943
```

Solution: count characters

```

1  text = ""
2  This is a very long text.
3  OK, maybe it is not that long after all.
4  ""
5
6  # print(text)
7  count = {}
8
9  for char in text:
10     if char == '\n':
11         continue
12     if char not in count:
13         count[char] = 1
14     else:
15         count[char] += 1
16
17  for key in sorted( count.keys() ):
18     print("'{}' {}".format(key, count[key]))

```

- We need to store the counter somewhere. We could use two lists for that, but that would give a complex solution that runs in $O(n^2)$ time.
- Besides, we are in the chapter about dictionaries so probably we better use a dictionary.
- In the count dictionary we each key is going to be one of the characters and the respective value will be the number of times it appeared.
- So if our string is "aabx" then we'll end up with

```

1  {
2      "a": 2,
3      "b": 1,
4      "x": 1,
5  }

```

- The `for in` loop on a string will iterate over it character by character (even if we don't call our variable `char`).
- We check if the current character is a newline `\n` and if it we call `continue` to skip the rest of the iteration. We don't want to count newlines.
- Then we check if we have already seen this character. That is, it is already one of the keys in the count dictionary. If not yet, then we add it and put 1 as the values. After all we saw one copy of this character. If we have already seen this character (we get to the `else` part) then we increment the counter for this character.
- We are done now with the data collection.

- In the second loop we go over the keys of the dictionary, that is the characters we have encountered. We sort them in ASCII order.
- Then we print each one of them and the respective value, the number of times the character was found.

Solution: count characters with default dict

```
1  from collections import defaultdict
2
3  text = """
4  This is a very long text.
5  OK, maybe it is not that long after all.
6  """
7
8  # print(text)
9  count = defaultdict(int)
10
11 for char in text:
12     if char == '\n':
13         continue
14     count[char] += 1
15
16 for key in sorted( count.keys() ):
17     print("'{}' {}".format(key, count[key]))
```

- The previous solution can be slightly improved by using defaultdict from the collections module.
- `count = defaultdict(int)` creates an empty dictionary that has the special feature that if you try to use a key that does not exist, it pretends that it exists and that it has a value 0.
- This allows us to remove the condition checking if the character was already seen and just increment the counter. The first time we encounter a character the dictionary will pretend that it was already there with value 0 so everything will work out nicely.

Solution: count words

```
1 words = ['Wombat', 'Rhino', 'Sloth', 'Tarantula', 'Sloth', 'Rhino', 'Sloth']
2
3 counter = {}
4 for word in words:
5     if word not in counter:
6         counter[word] = 0
7     counter[word] += 1
8
9 for word in counter:
10     print("{}:{}".format(word, counter[word]))
```

```
1 from collections import Counter
2
3 words = ['Wombat', 'Rhino', 'Sloth', 'Tarantula', 'Sloth', 'Rhino', 'Sloth']
4
5 cnt = Counter()
6 for word in words:
7     cnt[word] += 1
8
9 print(cnt)
10 for w in cnt.keys():
11     print("{}:{}".format(w, cnt[w]))
```

```
1 from collections import defaultdict
2
3 words = ['Wombat', 'Rhino', 'Sloth', 'Tarantula', 'Sloth', 'Rhino', 'Sloth']
4
5 dd = defaultdict(lambda : 0)
6 for word in words:
7     dd[word] += 1
8
9 print(dd)
10 for word in dd.keys():
11     print("{}:{}".format(word, dd[word]))
```

Solution: count words in file

```
1  import sys
2
3  filename = 'README'
4  if len(sys.argv) > 1:
5      filename = sys.argv[1]
6  print(filename)
7
8  count = {}
9
10 with open(filename) as fh:
11     for full_line in fh:
12         line = full_line.rstrip('\n')
13         line = line.lower()
14         for word in line.split():
15             if word == '':
16                 continue
17             if word not in count:
18                 count[word] = 0
19
20             count[word] += 1
21
22 for word in sorted(count):
23     print("{:13} {:>2}".format(word, count[word]))
```

Solution: Apache log

```
1  filename = 'examples/apache_access.log'
2
3  count = {}
4
5  with open(filename) as fh:
6      for line in fh:
7          space = line.index(' ')
8          ip = line[0:space]
9          if ip in count:
10             count[ip] += 1
11          else:
12             count[ip] = 1
13
14 for ip in count:
15     print("{:16} {:>3}".format(ip, count[ip]))
```

Solution: Combine lists again

```
1 c = {}
2 with open('examples/files/a.txt') as fh:
3     for line in fh:
4         k, v = line.rstrip("\n").split("=")
5         if k in c:
6             c[k] += int(v)
7         else:
8             c[k] = int(v)
9
10 with open('examples/files/b.txt') as fh:
11     for line in fh:
12         k, v = line.rstrip("\n").split("=")
13         if k in c:
14             c[k] += int(v)
15         else:
16             c[k] = int(v)
17
18
19 with open('out.txt', 'w') as fh:
20     for k in sorted(c.keys()):
21         fh.write("{}={}\n".format(k, c[k]))
```

Solution: counting DNA bases

```
1 seq = "ACTNGTGCTYGATRGTAGCYXGTN"
2 count = {}
3 for c in seq:
4     if c not in count:
5         count[c] = 0
6     count[c] += 1
7
8 for c in sorted(count.keys()):
9     print("{} {} - {:>5.2f} %".format(c, count[c], 100 * count[c]/len(seq)))
10
11 # >5 is the right alignment of 5 places
12 # .2f is the floating point with 2 digits after the floating point
```

Solution: Count Amino Acids

Generate random DNA sequence

```
1 import sys
2 import random
3
4 if len(sys.argv) != 2:
5     exit("Need a number")
6 count = int(sys.argv[1])
7
8 dna = []
9 for _ in range(count):
10     dna.append(random.choice(['A', 'C', 'T', 'G']))
11 print(''.join(dna))
```

```
1 dna = 'CACCCATGAGATGTCTTAACGCTGCTTTCATTATAGCCG'
2
3 aa_by_codon = {
4     'ACG' : '?',
5     'CAC' : 'Histidin',
6     'CAU' : 'Histidin',
7     'CCA' : 'Proline',
8     'CCG' : 'Proline',
9     'GAT' : '?',
10    'GTC' : '?',
11    'TGA' : '?',
12    'TTA' : '?',
13    'CTG' : '?',
14    'CTT' : '?',
15    'TCA' : '?',
16    'TAG' : '?',
17    '#...'
18 }
19
20 count = {}
21
22 for i in range(0, len(dna)-2, 3):
23     codon = dna[i:i+3]
24     #print(codon)
25     aa = aa_by_codon[codon]
```

```
26     if aa not in count:
27         count[aa] = 0
28     count[aa] += 1
29
30 for aa in sorted(count.keys()):
31     print("{} {}".format(aa, count[aa]))
```

Loop over dictionary keys

Looping over the “dictionary” is just like looping over the keys.

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 for k in user:
7     print("{} -> {}".format(k, user[k]))
8
9 # lname -> Bar
10 # fname -> Foo
```

Do not change dictionary in loop

```
1 user = {
2     'fname': 'Foo',
3     'lname': 'Bar',
4 }
5
6 for k in user.keys():
7     user['email'] = 'foo@bar.com'
8     print(k)
9
10 print('-----')
11
12 for k in user:
13     user['birthdate'] = '1991'
14     print(k)
15
16 # lname
17 # fname
```

```
18 # -----
19 # lname
20 # Traceback (most recent call last):
21 #   File "examples/dictionary/change_in_loop.py", line 13, in <module>
22 #     for k in user:
23 # RuntimeError: dictionary changed size during iteration
```

Default Dict

```
1 counter = {}
2
3 word = 'eggplant'
4
5 counter[word] += 1
6 # counter[word] = counter[word] + 1

1 Traceback (most recent call last):
2   File "counter.py", line 5, in <module>
3     counter[word] += 1
4   KeyError: 'eggplant'

1 counter = {}
2
3 word = 'eggplant'
4
5 if word not in counter:
6     counter[word] = 0
7 counter[word] += 1
8
9 print(counter)

1 {'eggplant': 1}
```

```
1  from collections import defaultdict
2
3  counter = defaultdict(int)
4
5  word = 'eggplant'
6
7  counter[word] += 1
8
9  print(counter)
```

```
1  defaultdict(<class 'int'>, {'eggplant': 1})
```

Sets

sets

- Sets in Python are used when we are primarily interested in operations that we know from the [sets theory](#)⁶⁷.
- See also the [Venn diagrams](#)⁶⁸.
- In day to day speech we often use the word “group” instead of “set” even though they are not the same.
- What are the common elements of two set (two groups).
- Is one group (set) the subset of the other?
- What are all the elements that exist in both groups (sets)?
- What are the elements that exist in exactly one of the groups (sets)?

set operations

- set
 - issubset
 - intersection
 - symmetric difference
 - union
 - relative complement
-
- [stdtypes: set](#)⁶⁹

set intersection

⁶⁷[https://en.wikipedia.org/wiki/Set_\(mathematics\)](https://en.wikipedia.org/wiki/Set_(mathematics))

⁶⁸https://en.wikipedia.org/wiki/Venn_diagram

⁶⁹<http://docs.python.org/library/stdtypes.html#set>

```
1 english = set(['door', 'car', 'lunar', 'era'])
2 spanish = set(['era', 'lunar', 'hola'])
3
4 print('english: ', english)
5 print('spanish: ', spanish)
6
7 both = english.intersection(spanish)
8 print(both)
```

- intersection returns the elements that are in both sets.

```
1 english: {'car', 'lunar', 'era', 'door'}
2 spanish: {'lunar', 'era', 'hola'}
3 {'lunar', 'era'}
```

set subset

```
1 english = set(['door', 'car', 'lunar', 'era'])
2 spanish = set(['era', 'lunar', 'hola'])
3
4 words = set(['door', 'lunar'])
5
6
7 print('issubset: ', words.issubset( english ))
8 print('issubset: ', words.issubset( spanish ))
```

- intersection returns the elements that are in both sets.

```
1 issubset: True
2 issubset: False
```

set symmetric difference

```
1 english = set(['door', 'car', 'lunar', 'era'])
2 spanish = set(['era', 'lunar', 'hola'])
3
4 diff = english.symmetric_difference(spanish)
5 print('symmetric_difference: ', diff)
```

- Symmetric difference is all the elements in either one of the sets, but not in both. “the ears of the elephant”.

```
1 symmetric_difference: {'door', 'hola', 'car'}
```

set union

```
1 english = set(['door', 'car', 'lunar', 'era'])
2 spanish = set(['era', 'lunar', 'hola'])
3
4 all_the_words = english.union(spanish)
5
6 print(english)
7 print(spanish)
8 print(all_the_words)
```

```
1 {'era', 'door', 'lunar', 'car'}
2 {'era', 'hola', 'lunar'}
3 {'era', 'door', 'car', 'hola', 'lunar'}
```

set relative complement

```
1 english = set(['door', 'car', 'lunar', 'era'])
2 spanish = set(['era', 'lunar', 'hola'])
3
4
5 eng = english - spanish
6 spa = spanish - english
7
8 print(spa)
9 print(eng)
10
11 print(english)
12 print(spanish)
```

```
1 {'hola'}
2 {'door', 'car'}
3 {'door', 'era', 'car', 'lunar'}
4 {'hola', 'era', 'lunar'}
```

set examples

```
1 things = set(['table', 'chair', 'door', 'chair', 'chair'])
2 print(things)
3 print(things.__class__)
4 print(things.__class__.__name__)
5
6 if 'table' in things:
7     print("has table")
```

```
1 {'door', 'chair', 'table'}
2 <class 'set'>
3 set
4 has table
```

defining an empty set

```
1 objects = set()
2 print(objects)
```

```
1 set()
```

```
1 set([])
```

Adding an element to a set (add)

```
1  objects = set()
2  print(objects)
3
4  objects.add('Mars')
5  print(objects)
6
7  objects.add('Mars')
8  print(objects)
9
10 objects.add('Neptun')
11 print(objects)
```

```
1  set()
2  {'Mars'}
3  {'Mars'}
4  {'Neptun', 'Mars'}
```

In Python 2:

```
1  set([])
2  set(['Mars'])
3  set(['Mars'])
4  set(['Neptun', 'Mars'])
```

Merging one set into another set (update)

```
1  set(['Neptun', 'Mars'])
2
3
4  objects = set(['Mars', 'Jupiter', 'Saturn'])
5  internal = set(['Mercury', 'Venus', 'Earth', 'Mars'])
6
7  objects.update(internal)
8  print(objects)
9  print(internal)

1  {'Mars', 'Jupiter', 'Earth', 'Mercury', 'Saturn', 'Venus'}
2  {'Mars', 'Earth', 'Mercury', 'Venus'}
```

Functions (subroutines)

Defining simple function

```
1 def add(x, y):
2     z = x + y
3     return z
4
5 a = add(2, 3)
6 print(a)    # 5
7
8 q = add(23, 19)
9 print(q)    # 42
```

The function definition starts with the word “def” followed by the name of the function (“add” in our example), followed by the list of parameters in a pair of parentheses, followed by a colon “:”. Then the body of the function is indented to the right. The depth of indentation does not matter but it must be the same for all the lines of the function. When we stop the indentation and start a new expression on the first column, that’s what tells Python that the function definition has ended.

Defining a function

```
1 def sendmail(From, To, Subject, Content):
2     print('From:', From)
3     print('To:', To)
4     print('Subject:', Subject)
5     print('')
6     print(Content)
7
8 sendmail('gabor@szabgab.com',
9         'szabgab@gmail.com',
10        'self message',
11        'Has some content too')
```

Positional parameters.

Parameters can be named

```
1 def sendmail(From, To, Subject, Content):
2     print('From:', From)
3     print('To:', To)
4     print('Subject:', Subject)
5     print('')
6     print(Content)
7
8 sendmail(
9     Subject = 'self message',
10    Content = 'Has some content too',
11    From = 'gabor@szabgab.com',
12    To = 'szabgab@gmail.com',
13 )
```

The parameters of every function can be passed either as positional parameters or as named parameters.

Mixing positional and named parameters

```
1 def sendmail(From, To, Subject, Content):
2     print('From:', From)
3     print('To:', To)
4     print('Subject:', Subject)
5     print('')
6     print(Content)
7
8 sendmail(
9     Subject = 'self message',
10    Content = 'Has some content too',
11    To = 'szabgab@gmail.com',
```

```
12     'gabor@szabgab.com',
13 )
```

```
1 def sendmail(From, To, Subject, Content):
2     print('From:', From)
3     print('To:', To)
4     print('Subject:', Subject)
5     print('')
6     print(Content)
7
8 sendmail(
9     'gabor@szabgab.com',
10    Subject = 'self message',
11    Content = 'Has some content too',
12    To = 'szabgab@gmail.com',
13 )
```

```
1 File "examples/functions/named_and_positional_params.py", line 14
2     'gabor@szabgab.com',
3     ^
4 SyntaxError: positional argument follows keyword argument
```

Default values

```
1 def prompt(question, retry=3):
2     while retry > 0:
3         inp = input('{} ({}): '.format(question, retry))
4         if inp == 'my secret':
5             return True
6         retry -= 1
7     return False
8
9 print(prompt("Type in your password"))
10
11 print(prompt("Type in your secret", 1))
```

Function parameters can have default values. In such case the parameters are optional. In the function declaration, the parameters with the default values must come last.

In the call, the order among these arguments does not matter, and they are optional anyway.

Several defaults, using names

Parameters with defaults must come at the end of the parameter declaration.

```
1 def f(a, b=2, c=3):
2     print(a, b , c)
3
4 f(1)                # 1 2 3
5 f(1, b=0)           # 1 0 3
6 f(1, c=0)           # 1 2 0
7 f(1, c=0, b=5)      # 1 5 0
8
9 # f(b=0, 1)
10 # would generate:
11 # SyntaxError: non-keyword arg after keyword arg
12
13 f(b=0, a=1)         # 1 0 3
```

There can be several parameters with default values.
They are all optional and can be given in any order after the positional arguments.

Arbitrary number of arguments *

The values arrive as tuple.

```
1 def mysum(*numbers):
2     print(numbers)
3     total = 0
4     for s in numbers:
5         total += s
6     return total
7
8 print(mysum(1))
9 print(mysum(1, 2))
10 print(mysum(1, 1, 1))
11
12 x = [2, 3, 5, 6]
13 print(mysum(*x))
```

```
1 (1,)
2 1
3 (1, 2)
4 3
5 (1, 1, 1)
6 3
```

Fixed parameters before the others

The `*numbers` argument can be preceded by any number of regular arguments

```
1 def mysum(op, *numbers):
2     print(numbers)
3     if op == '+':
4         total = 0
5     elif op == '*':
6         total = 1
7     else:
8         raise Exception('invalid operator {}'.format(op))
9
10    for s in numbers:
11        if op == '+':
12            total += s
13        elif op == '*':
```

```
14         total *= s
15
16     return total
17
18 print(mysum('+', 1))
19 print(mysum('+', 1, 2))
20 print(mysum('+', 1, 1, 1))
21 print(mysum('*', 1, 1, 1))
```

```
1  (1,)
2  1
3  (1, 2)
4  3
5  (1, 1, 1)
6  3
7  (1, 1, 1)
8  1
```

Arbitrary key-value pairs in parameters **

```
1 def f(**kw):
2     print(kw)
3
4 f(a = 23, b = 12)
```

```
1 {'a': 23, 'b': 12}
```

Extra key-value pairs in parameters

```
1 def f(name, **kw):
2     print(name)
3     print(kw)
4
5 f(name="Foo", a = 23, b = 12)
6
7 # Foo
8 # {'a': 23, 'b': 12}
```

```
1 Foo
2 {'a': 23, 'b': 12}
```

Every parameter option

```
1 def f(op, count = 0, *things, **kw):
2     print(op)
3     print(count)
4     print(things)
5     print(kw)
6
7 f(2, 3, 4, 5, a = 23, b = 12)
8
9 # 2
10 # 3
11 # (4, 5)
12 # {'a': 23, 'b': 12}
```

Duplicate declaration of functions (multiple signatures)

```
1 def add(x, y):
2     return x*y
3
4 print(add(2, 3)) # 6
5
6 def add(x):
7     return x+x
8
9 # add(2, 3)
10 # TypeError: add() takes exactly 1 argument (2 given)
11
12 print(add(2)) # 4
```

The second declaration silently overrides the first declaration.

- [pylint](http://www.pylint.org/)⁷⁰ can find such problems, along with a bunch of others.

Recursive factorial

⁷⁰<http://www.pylint.org/>

```
1  n! = n * (n-1) ... * 1
2
3  0! = 1
4  n! = n * (n-1)!
5
6  f(0) = 1
7  f(n) = n * f(n-1)

1  def f(n):
2      if n == 0:
3          return 1
4      return n * f(n-1)
5
6  print(f(1))    # 1
7  print(f(2))    # 2
8  print(f(3))    # 6
9  print(f(4))    # 24
```

Recursive Fibonacci

```
1  fib(1) = 1
2  fib(2) = 1
3  fib(n) = fib(n-1) + fib(n-2)

1  def fib(n):
2      if n == 1:
3          return 1
4      if n == 2:
5          return 1
6      return fib(n-1) + fib(n-2)
7
8  print(3, fib(3))    # 2
9  print(30, fib(30))  # 832040
```

Python also supports recursive functions.

Non-recursive Fibonacci

```
1 def fib(n):
2     if n == 1:
3         return [1]
4     if n == 2:
5         return [1, 1]
6     fibs = [1, 1]
7     for i in range(2, n):
8         fibs.append(fibs[-1] + fibs[-2])
9     return fibs
10
11 print(fib(1)) # [1]
12 print(fib(2)) # [1, 1]
13 print(fib(3)) # [1, 1, 2]
14 print(fib(10)) # [1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

Unbound recursion

- In order to protect us from unlimited recursion, Python limits the depth of recursion:

```
1 def recursion(n):
2     print(f"In recursion {n}")
3     recursion(n+1)
4
5 recursion(1)

1 ...
2 In recursion 995
3 In recursion 996
4 Traceback (most recent call last):
5   File "recursion.py", line 7, in <module>
6     recursion(1)
7   File "recursion.py", line 5, in recursion
8     recursion(n+1)
9   File "recursion.py", line 5, in recursion
10    recursion(n+1)
11   File "recursion.py", line 5, in recursion
12    recursion(n+1)
13   [Previous line repeated 992 more times]
14   File "recursion.py", line 4, in recursion
15     print(f"In recursion {n}")
16 RecursionError: maximum recursion depth exceeded while calling a Python object
```

Variable assignment and change - Immutable

Details showed on the next slide

```
1  a = 42      # number or string
2  b = a       # This is a copy
3  print(a)    # 42
4  print(b)    # 42
5  a = 1
6  print(a)    # 1
7  print(b)    # 42
8
9  a = (1, 2)   # tuple
10 b = a        # this is a copy
11 print(a)     # (1, 2)
12 print(b)     # (1, 2)
13 # a[0] = 42  TypeError: 'tuple' object does not support item assignment
14 a = (3, 4, 5)
15 print(a)     # (3, 4, 5)
16 print(b)     # (1, 2)
```

Variable assignment and change - Mutable

```
1  a = [5, 6]
2  b = a        # this is a copy of the *reference* only
3               # if we change the list in a, it will
4               # change the list connected to b as well
5  print(a)     # [5, 6]
6  print(b)     # [5, 6]
7  a[0] = 1
8  print(a)     # [1, 6]
9  print(b)     # [1, 6]
10
11
12 a = {'name' : 'Foo'}
13 b = a        # this is a copy of the *reference* only
14             # if we change the dictionary in a, it will
15             # change the dictionary connected to b as well
16 print(a)     # {'name' : 'Foo'}
17 print(b)     # {'name' : 'Foo'}
18 a['name'] = 'Jar Jar'
```

```
19 print(a)      # {'name' : 'Jar Jar'}
20 print(b)      # {'name' : 'Jar Jar'}
```

Parameter passing of functions

```
1  x = 3
2
3  def inc(n):
4      n += 1
5      return n
6
7  print(x)      # 3
8  print(inc(x)) # 4
9  print(x)      # 3
```

Passing references

```
1  numbers = [1, 2, 3]
2
3  def update(x):
4      x[0] = 23
5
6  def change(y):
7      y = [5, 6]
8      return y
9
10 print(numbers)      # [1, 2, 3]
11
12 update(numbers)
13 print(numbers)      # [23, 2, 3]
14
15 print(change(numbers)) # [5, 6]
16 print(numbers)      # [23, 2, 3]
```

Function documentation

```
1 def f(name):
2     """
3     The documentation
4     should have more than one lines.
5     """
6     print(name)
7
8
9 f("hello")
10 print(f.__doc__)
```

Immediately after the definition of the function, you can add a string - it can be a “” string to spread multiple lines - that will include the documentation of the function. This string can be accessed via the **doc** (2+2 underscores) attribute of the function. Also, if you ‘import’ the file - as a module - in the interactive prompt of Python, you will be able to read this documentation via the **help()** function. **help(mydocs)** or **help(mydocs.f)** in the above case.

Sum ARGV

```
1 import sys
2
3 def mysum(*numbers):
4     print(numbers)
5     total = 0
6     for s in numbers:
7         total += s
8     return total
9
10 v = [int(x) for x in sys.argv[1:]]
11 r = mysum(*v)
12 print(r)
```

Copy-paste code

```
1 a = [2, 3, 93, 18]
2 b = [27, 81, 11, 35]
3 c = [32, 105, 1]
4
5 total_a = 0
6 for v in a:
7     total_a += v
8 print("sum of a: {} average of a: {}".format(total_a, total_a / len(a)))
9
10 total_b = 0
11 for v in b:
12     total_b += v
13 print("sum of b: {} average of b: {}".format(total_b, total_b / len(b)))
14
15 total_c = 0
16 for v in c:
17     total_c += v
18 print("sum of c: {} average of c: {}".format(total_c, total_c / len(a)))
```

```
1 sum of a: 116 average of a: 29.0
2 sum of b: 154 average of b: 38.5
3 sum of c: 138 average of c: 34.5
```

Did you notice the bug?

Copy-paste code fixed

```
1 a = [2, 3, 93, 18]
2 b = [27, 81, 11, 35]
3 c = [32, 105, 1]
4
5 def calc(numbers):
6     total = 0
7     for v in numbers:
8         total += v
9     return total, total / len(numbers)
10
11 total_a, avg_a = calc(a)
12 print("sum of a: {} average of a: {}".format(total_a, avg_a))
13
14 total_b, avg_b = calc(b)
```

```

15 print("sum of b: {} average of b: {}".format(total_b, avg_b))
16
17
18 total_c, avg_c = calc(c)
19 print("sum of c: {} average of c: {}".format(total_c, avg_c))

```

```

1 sum of a: 116 average of a: 29.0
2 sum of b: 154 average of b: 38.5
3 sum of c: 138 average of c: 46.0

```

Copy-paste code further improvement

```

1 data = {
2     'a': [2, 3, 93, 18],
3     'b': [27, 81, 11, 35],
4     'c': [32, 105, 1],
5 }
6
7 def calc(numbers):
8     total = 0
9     for v in numbers:
10         total += v
11     return total, total / len(numbers)
12
13 total = {}
14 avg = {}
15 for name, numbers in data.items():
16     total[name], avg[name] = calc(numbers)
17     print("sum of {}: {} average of {}: {}".format(name, total[name], name, avg[name]\
18 ))

```

Palindrome

An iterative and a recursive solution

```

1  def is_palindrome(s):
2      if s == '':
3          return True
4      if s[0] == s[-1]:
5          return is_palindrome(s[1:-1])
6      return False
7
8  def iter_palindrome(s):
9      for i in range(0, int(len(s) / 2)):
10         if s[i] != s[-(i+1)]:
11             return False
12     return True
13
14 print(is_palindrome(''))      # True
15 print(is_palindrome('a'))    # True
16 print(is_palindrome('ab'))   # False
17 print(is_palindrome('aa'))   # True
18 print(is_palindrome('aba'))  # True
19 print(is_palindrome('abc'))  # False
20
21 print()
22 print(iter_palindrome(''))    # True
23 print(iter_palindrome('a'))   # True
24 print(iter_palindrome('ab'))  # False
25 print(iter_palindrome('aa'))  # True
26 print(iter_palindrome('aba')) # True
27 print(iter_palindrome('abc')) # False

```

Exercise: statistics

Write a function that will accept any number of numbers and return a list of values:

- The sum
- Average
- Minimum
- Maximum

Exercise: recursive

Give a bunch of files that has list of requirement in them.

Process them recursively and print the resulting full list of requirements

```
1 b
2 c
3 d
```

```
1 e
2 d
```

```
1 f
2 g
```

```
1 $ python traversing_dependency_tree.py a
2
3 Processing a
4 Processing b
5 Processing e
6 Processing d
7 Processing c
8 Processing f
9 Processing g
10 Processing d
```

Exercise: Tower of Hanoi

[Tower of Hanoi](https://en.wikipedia.org/wiki/Tower_of_Hanoi)⁷¹

Exercise: Merge and Bubble sort

- Implement [bubble sort](https://en.wikipedia.org/wiki/Bubble_sort)⁷²
- Implement [merge sort](https://en.wikipedia.org/wiki/Merge_sort)⁷³

Solution: statistics

⁷¹https://en.wikipedia.org/wiki/Tower_of_Hanoi

⁷²https://en.wikipedia.org/wiki/Bubble_sort

⁷³https://en.wikipedia.org/wiki/Merge_sort

```
1 def stats(*numbers):
2     total = 0
3
4     average = None # there might be better solutions here!
5     minx = None
6     maxx = None
7
8     for val in numbers:
9         total += val
10        if minx == None:
11            minx = maxx = val
12        if minx > val:
13            minx = val
14        if maxx < val:
15            maxx = val
16
17    if len(numbers):
18        average = total / len(numbers)
19
20
21    return total, average, minx, maxx
22
23
24 ttl, avr, smallest, largest = stats(3, 5, 4)
25
26 print(ttl)
27 print(avr)
28 print(smallest)
29 print(largest)
```

Solution: recursive

```

1  import sys
2  import os
3
4  if len(sys.argv) < 2:
5      exit("Usage: {} NAME".format(sys.argv[0]))
6
7  start = sys.argv[1]
8
9  def get_dependencies(name):
10     print("Processing {}".format(name))
11
12     deps = set(name)
13     filename = name + ".txt"
14     if not os.path.exists(filename):
15         return deps
16
17     with open(filename) as fh:
18         for line in fh:
19             row = line.rstrip("\n")
20             deps.add(row)
21             deps.update( get_dependencies(row) )
22
23     return deps
24
25 dependencies = get_dependencies(start)
26 print(dependencies)

```

Solution: Tower of Hanoi

```

1  def check():
2      for loc in hanoi.keys():
3          if hanoi[loc] != sorted(hanoi[loc], reverse=True):
4              raise Exception(f"Incorrect order in {loc}: {hanoi[loc]}")
5
6  def move(depth, source, target, helper):
7      if depth > 0:
8          move(depth-1, source, helper, target)
9
10         val = hanoi[source].pop()
11         hanoi[target].append(val)
12         print(f"Move {val} from {source} to {target}    Status A:{str(hanoi['A']):10}\
13         B:{str(hanoi['B']):10}  C:{str(hanoi['C']):10}")

```

```

14         check()
15
16         move(depth-1, helper, target, source)
17     check()
18
19     hanoi = {
20         'A': [4, 3, 2, 1],
21         'B': [],
22         'C': [],
23     }
24
25     check()
26     move(len(hanoi['A']), 'A', 'C', 'B')
27     check()

```

Solution: Merge and Bubble sort

```

1  def recursive_bubble_sort(data):
2      data = data[:]
3      if len(data) == 1:
4          return data
5
6      last = data.pop()
7      sorted_data = recursive_bubble_sort(data)
8      for i in range(len(sorted_data)):
9          if last > sorted_data[i]:
10             sorted_data.insert(i, last)
11             break
12     else:
13         sorted_data.append(last)
14     return sorted_data
15
16 def iterative_bubble_sort(data):
17     data = data[:]
18     for end in (range(len(data)-1, 0, -1)):
19         for i in range(end):
20             if data[i] < data[i+1]:
21                 data[i], data[i+1] = data[i+1], data[i]
22     return data
23
24
25 old = [1, 5, 2, 4, 8]

```

```
26 new1 = recursive_bubble_sort(old)
27 new2 = iterative_bubble_sort(old)
28 print(old)
29 print(new1)
30 print(new2)
```

Modules

Before modules

```
1 def add(a, b):  
2     return a + b  
3  
4  
5 z = add(2, 3)  
6 print(z)      # 5
```

Create modules

A module is just a Python file with a set of functions that us usually not used by itself. For example the “my_calculator.py”.

```
1 def add(a, b):  
2     return a + b
```

A user made module is loaded exactly the same way as the built-in module.
The functions defined in the module are used as if they were methods.

```
1 import my_calculator  
2  
3 z = my_calculator.add(2, 3)  
4  
5 print(z)  # 5
```

We can import specific functions to the current name space (symbol table) and then we don't need to prefix it with the name of the file every time we use it. This might be shorter writing, but if we import the same function name from two different modules then they will overwrite each other. So I usually prefer loading the module as in the previous example.

```
1 from my_calculator import add
2
3 print(add(2, 3)) # 5
```

path to load modules from - The module search path

1. The directory where the main script is located.
2. The directories listed in PYTHONPATH environment variable.
3. Directories of standard libraries.
4. Directories listed in .pth files.
5. The site-packages home of third-party extensions.

sys.path - the module search path

```
1 import sys
2
3 print(sys.path)

1 ['/Users/gabor/work/training/python/examples/package',
2  '/Users/gabor/python/lib/python2.7/site-packages/crypto-1.1.0-py2.7.egg',
3  ...
4  '/Library/Python/2.7/site-packages', '/usr/local/lib/python2.7/site-packages']
5 [Finished in 0.112s]
```

Flat project directory structure

If our executable scripts and our modules are all in the same directory then we don't have to worry about the directory of the script is included in the list of places where "import" is looking for the files to be imported.

```
1 project/  
2     script_a.py  
3     script_b.py  
4     my_module.py
```

Absolute path

If we would like to load a module that is not installed in one of the standard locations, but we know where it is located on our disk, we can set the "sys.path" to the absolute path to this directory. This works on the specific computer, but if you'd like to distribute the script to other computers you'll have to make sure the module to be loaded is installed in the same location or you'll have to update the script to point to the location of the module in each computer. Not an ideal solution.

```
1 import sys  
2 sys.path.insert(0, "/home/foobar/python/libs")  
3  
4 # import module_name
```

Relative path

```
1 ../project_root/  
2     bin/relative_path.py  
3     lib/my_module.py
```

We can use a directory structure that is more complex than the flat structure we had earlier. In this case the location of the modules relatively to the scripts is fixed. In this case it is “../lib”. We can compute the relative path in each of our scripts. That will ensure we pick up the right module every time we run the script. Regardless of the location of the whole project tree.

```
1 print("Importing my_module")

1 import os, sys
2
3 # import my_module    # ImportError: No module named my_module
4
5 print(__file__)    # examples/sys/bin/relative_path.py
6 project_root = os.path.dirname(os.path.dirname(os.path.abspath(__file__)))
7
8 mypath = os.path.join(project_root, 'lib')
9 print(mypath) # /Users/gabor/work/training/python/examples/sys/../lib
10 sys.path.insert(0, mypath)
11
12 import my_module    # Importing my_module
```

Python modules are compiled

When libraries are loaded they are automatically compiled to .pyc files. This provides moderate code-hiding and load-time speed-up. Not run-time speed-up. Starting from Python 3.2 the pyc files are saved in the `__pycache__` directory.

How “import” and “from” work?

1. Find the file to load.
2. Compile to bytecode if necessary and save the bytecode if possible.
3. Run the code of the file loaded.
4. Copy names from the imported module to the importing namespace.

Runtime loading of modules

```
1 def hello():
2     print("Hello World")
3
4 print("Loading mygreet")

1 print("Start running")  # Start running
2
3 import mygreet          # Loading mygreet
4
5 mygreet.hello()         # Hello World
6
7 print("DONE")           # DONE
```

Conditional loading of modules

```
1 import random
2
3 print("Start running")
4 name = input("Your name:")
5
6 if name == "Foo":
7     import mygreet
8     mygreet.hello()
9 else:
10    print('No loading')
11
12
13 print("DONE")
```

Duplicate importing of functions

```
1  from mycalc import add
2  print(add(2, 3)) # 5
3
4  from mymath import add
5  print(add(2, 3)) # 6
6
7
8  from mycalc import add
9  print(add(2, 3)) # 5
```

The second declaration silently overrides the first declaration.

[pylint](#)⁷⁴ can find such problems, along with a bunch of others.

Script or library

We can have a file with all the functions implemented and then launch the `run()` function only if the file was executed as a stand-alone script.

```
1  def run():
2      print("run in ", __name__)
3
4  print("Name space in mymodule.py ", __name__)
5
6  if __name__ == '__main__':
7      run()
```

```
1  $ python mymodule.py
2  Name space in mymodule.py __main__
3  run in __main__
```

Script or library - import

⁷⁴<http://www.pylint.org/>

If it is imported by another module then it won't run automatically. We have to call it manually.

```
1 import mymodule
2
3 print("Name space in import_mymodule.py ", __name__)
4 mymodule.run()
```

```
1 $ python import_mymodule.py
2 Name space in mymodule.py mymodule
3 Name space in import_mymodule.py __main__
4 run in mymodule
```

Script or library - from import

```
1 from mymodule import run
2
3 print("Name space in import_mymodule.py ", __name__)
4 run()
```

```
1 $ python import_from_mymodule.py
2 Name space in mymodule.py mymodule
3 Name space in import_mymodule.py __main__
4 run in mymodule
```

assert to verify values

```

1 def add(x, y):
2     return x * y
3
4 for x, y, z in [(2, 2, 4), (9, 2, 11), (2, 3, 5)]:
5     print(f"add({x}, {y}) == {z}")
6     if add(x, y) != z:
7         raise Exception(f"add({x}, {y}) != {z}")
8         #raise AssertionError

```

[doctest](https://docs.python.org/3/library/doctest.html)⁷⁵

Scope of import

```

1 def div(a, b):
2     return a/b

1 from __future__ import print_function
2 from __future__ import division
3
4 import mydiv
5
6 print(mydiv.div(3, 2))    # 1
7
8 print(3/2)                # 1.5

```

⁷⁵<https://docs.python.org/3/library/doctest.html>

The importing of functions, and the changes in the behavior of the compiler are file specific. In this case the change in the behavior of division is only visible in the division.py script, but not in the mydiv.py module.

Export import

- `from mod import a,b,_c` - import 'a', 'b', and '_c' from 'mod'
- `from mod import *` - import every name listed in **all** of 'mod' if **all** is available.
- `from mod import *` - import every name that does NOT start with `_` (if **all** is not available)
- `import mod` - import 'mod' and make every name in 'mod' accessible as 'mod.a', and 'mod._c'

```
1 def a():
2     return "in a"
3
4 b = "value of b"
5
6 def _c():
7     return "in _c"
8
9 def d():
10    return "in d"
```

```
1 from my_module import a,b,_c
2
3 print(a())    # in a
4 print(b)      # value of b
5 print(_c())   # in _c
6
7 print(d())
8 # Traceback (most recent call last):
9 #   File ".../examples/modules/x.py", line 7, in <module>
10 #       print(d())
11 # NameError: name 'd' is not defined
```

```
1  from my_module import *
2
3  print(a())      # in a
4  print(b)        # value of b
5
6  print(d())      # in d
7
8
9  print(_c())
10
11  # Traceback (most recent call last):
12  #   File ".../examples/modules/y.py", line 9, in <module>
13  #     print(_c())    # in _c
14  # NameError: name '_c' is not defined
```

Export import with all

```
1  __all__ = ['a', '_c']
2
3  def a():
4      return "in a"
5
6  b = "value of b"
7
8  def _c():
9      return "in _c"
10
11 def d():
12     return "in d"
```

```
1  from my_module2 import *
2
3  print(a())      # in a
4  print(_c())     # in _c
5
6  print(b)
7
8  # Traceback (most recent call last):
9  #   File ".../examples/modules/z.py", line 7, in <module>
10  #     print(b)      # value of b
11  # NameError: name 'b' is not defined
```

import module

```
1 import my_module
2
3 print(my_module.a())    # in a
4 print(my_module.b)      # value of b
5 print(my_module._c())   # in _c
6 print(my_module.d())    # in d
```

Execute at import time

```
1 import lib
2
3 print("Hello")
```

```
1 print("import lib")
2
3 def do_something():
4     print("do something")
```

```
1 import lib
2 Hello
```

Import multiple times

```
1 import one
2 import two
3
4 print("Hello")
```

```
1 import common
2 print("loading one")
```

```
1 import common
2 print("loading two")
```

```
1 print("import common")
```

```
1 import common
2 loading one
3 loading two
4 Hello
```

Exercise: Number guessing

Take the number guessing game from the earlier chapter and move the internal `while()` loop to a function.

Once that's done, move the function out to a separate file and use it as a module.

Exercies: Scripts and modules

Take the number guessing game: if I run it as a script execute the whole game with repeated hidden numbers.

If I load it as a module, then let me call the function that runs a single game with one hidden number. We should be able to even pass the hidden number as a parameter.

Exercise: Module `my_sum`

- Create a file called `my_simple_math.py` with two functions: `div(a, b)`, `add(a, b)`, that will divide and add the two numbers respectively.
- Add another two functions called `test_div` and `test_add` that will test the above two functions using `assert`.
- Add code that will run the tests if someone execute `python my_simple_math.py` running the file as if it was a script.
- Create another file called `use_my_simple_math.py` that will use the functions from `my_math` module to calculate `2 + 5 * 7`
- Make sure when you run `python use_my_simple_math.py` the tests won't run.
- Add documentation to the “add” and “div” functions to examples that can be used with `doctest`.
- Can you run the tests when the file is loaded as a module?

Exercise: Convert your script to module

- Take one of your real script (from work). Create a backup copy.
- Change the script so it can be import-ed as a module and then it won't automatically execute anything, but that it still works when executed as a script.
- Add a new function to it called `self_test` and in that function add a few test-cases to your code using 'assert'.
- Write another script that will load your real file as a module and will run the `self_test`.
- Let me know what are the difficulties!

Exercise: Add doctests to your own code

- Pick a module from your own code and create a backup copy. (from work)
- Add a function called 'self_test' that uses 'assert' to test some of the real functions of the module.
- Add code that will run the 'self_test' when the file is executed as a script.
- Add documentation to one of the functions and convert the 'assert'-based tests to doctests.
- Convert the mechanism that executed the 'self_test' to run the doctests as well.
- Let me know what are the difficulties!

Solution: Module my_sum

```
1 def div(a, b):
2     '''
3     >>> div(8, 2)
4     4
5     '''
6     return a/b
7
8 def add(a, b):
9     '''
10    >>> add(2, 2)
11    4
12    '''
13    return a * b    # bug added on purpose!
14
15 def test_div():
16     assert div(6, 3) == 2
17     assert div(0, 10) == 0
18     assert div(-2, 2) == -1
```

```
19     #assert div(10, 0) == ??
20
21 def test_add():
22     assert add(2, 2) == 4
23     #assert add(1, 1) == 2
24
25
26 if __name__ == "__main__":
27     test_div()
28     test_add()

1 import my_simple_math
2 print(my_simple_math.my_sum(2, 3, 5))
3
4 print(dir(my_simple_math))
5 #my_sum_as_function.test_my_sum()
```

Regular Expressions

What are Regular Expressions (aka. Regexes)?

- An idea on how to match some pattern in some text.
- A tool/language that is available in many places.
- Has many different “dialects”
- Has many different modes of processing.
- The grand concept is the same.
- Uses the following symbols:

```
1  ( ) [ ] { } . * + ? ^ $ | - \ \d \s \w \A \Z \1 \2 \3
```

What are Regular Expressions good for?

- Decide if a string is part of a larger string.
- Validate the format of some value (string) (e.g. is it a decimal number?, is it a hex?)
- Find if there are repetitions in a string.
- Analyze a string and fetch parts of it given some loose description.
- Cut up a string into parts.
- Change parts of a string.

Examples

```
1  Is the input given by the user a number?
2
3  (BTW which one is a number:  23, 2.3,  2.3.4, 2.4e3, abc ?)
4
5  Is there a word in the file that is repeated 3 or more times?
6
7  Replaces all occurrences of Python or python by Java ...
8  ... but avoid replacing Monty Python.
9
10
11 Given a text message fetch all the phone numbers:
```

```
12 Fetch numbers that look like 09-1234567
13 then also fetch +972-2-1234567
14 and maybe also 09-123-4567
15
16
17 Check if in a given text passing your network there are credit card numbers....
18
19
20 Given a text find if the word "password" is in it and fetch the surrounding text.
21
22
23 Given a log file like this:
24
25 [Tue Jun 12 00:01:00 2019] - (3423) - INFO - ERROR log restarted
26 [Tue Jun 12 09:08:17 2019] - (3423) - INFO - System starts to work
27 [Tue Jun 13 08:07:16 2019] - (3423) - ERROR - Something is wrong
28
29 provide statistics on how many of the different levels of log messages
30 were seen. Separate the log messages into files.
```

Where can I use it ?

- grep, egrep
- Unix tools such as sed, awk, procmail
- vi, emacs, other editors
- text editors such as Multi-Edit
- .NET languages: C#, C++, VB.NET
- Java
- Perl
- **Python**
- PHP
- Ruby
- ...
- Word, Open Office ...
- PCRE

grep

grep gets a regex and one or more files. It goes over line-by-line all the files and displays the lines where the regex matched. A few examples:

```
1 grep python file.xml      # lines that have the string python in them in file.xml.
2 grep [34] file.xml       # lines that have either 3 or 4 (or both) in file.xml.
3 grep [34] *.xml          # lines that have either 3 or 4 (or both) in every xml file.
4 grep [0-9] *.xml         # lines with a digit in them.
5 egrep '\b[0-9]' *.xml    # only highlight digits that are at the beginning of a numbe\
6 r.
```

Regexes first match

```
1 import re
2
3 text = 'The black cat climed'
4 match = re.search(r'lac', text)
5 if match:
6     print("Matching")      # Matching
7     print(match.group(0))  # lac
8
9 match = re.search(r'dog', text)
10 if match:
11     print("Matching")
12 else:
13     print("Did NOT match")
14     print(match)          # None
```

The search method returns an object or **None**, if it could not find any match. If there is a match you can call the **group()** method. Passing 0 to it will return the actual substring that was matched.

Match numbers

```
1 import re
2
3 line = 'There is a phone number 12345 in this row and an age: 23'
4
5 match = re.search(r'\d+', line)
6 if match:
7     print(match.group(0)) # 12345
```

Use raw strings for regular expression: `r'a\d'`. Especially because `\` needs it.

- `\d` matches a digit.
- `+` is a quantifier and it tells `\d` to match one or more digits.

It matches the first occurrence.

Here we can see that the `group(0)` call is much more interesting than earlier.

Capture

```
1 import re
2
3 line = 'There is a phone number 12345 in this row and an age: 23'
4
5 match = re.search(r'age: \d+', line)
6 if match:
7     print(match.group(0)) # age: 23
8
9
10 match = re.search(r'age: (\d+)', line)
11 if match:
12     print(match.group(0)) # age: 23
13     print(match.group(1)) # 23      the first group of parentheses
14
15     print(match.groups()) # ('23',)
16     print(len(match.groups())) # 1
```

Parentheses in the regular expression can enclose any sub-expression.
Whatever this sub-expression matches will be saved and can be accessed using the `group()` method.

Capture more

```

1  import re
2
3  line = 'There is a phone number 12345 in this row and an age: 23'
4
5  match = re.search(r'(\w+): (\d+)', line)
6  if match:
7      print(match.group(0)) # age: 23
8      print(match.group(1)) # age      the first group of parentheses
9      print(match.group(2)) # 23      the second group of parentheses
10
11     # print(match.group(3)) # IndexError: no such group
12     print(match.groups()) # ('age', '23')
13     print(len(match.groups())) # 2

```

Some groups might match '' or even not match at all, in which case we get None in the appropriate match.group() call and in the match.groups() call

Capture even more

```

1  import re
2
3  line = 'There is a phone number 12345 in this row and an age: 23'
4
5  match = re.search(r'((\w+): (\d+))', line)
6  if match:
7      print(match.group(0)) # age: 23
8      print(match.group(1)) # age: 23
9      print(match.group(2)) # age
10     print(match.group(3)) # 23
11
12     print(match.groups()) # ('age: 23', 'age', '23')
13     print(len(match.groups())) # 3

```

findall

```
1 import re
2
3 line1 = 'There is a phone number 12345 in this row and another 42 number'
4 numbers1 = re.findall(r'\d+', line1)
5 print(numbers1) # ['12345', '42']
6
7 line2 = 'There are no numbers in this row. Not even one.'
8 numbers2 = re.findall(r'\d+', line2)
9 print(numbers2) # []
```

`re.findall` returns the matched substrings.

findall with capture

```
1 import re
2
3 line = 'There is a phone number 12345 in this row and another 42 number'
4 match = re.search(r'\w+ \d+', line)
5 if match:
6     print(match.group(0))    # number 12345
7
8 match = re.search(r'\w+ (\d+)', line)
9 if match:
10    print(match.group(0))    # number 12345
11    print(match.group(1))    # 12345
12
13 matches = re.findall(r'\w+ \d+', line)
14 print(matches) # ['number 12345', 'another 42']
15
16 matches = re.findall(r'\w+ (\d+)', line)
17 print(matches) # ['12345', '42']
```

findall with capture more than one

```
1 import re
2
3 line = 'There is a phone number 12345 in this row and another 42 number'
4 match = re.search(r'(\w+) (\d+)', line)
5 if match:
6     print(match.group(1))    # number
7     print(match.group(2))    # 12345
8
9 matches = re.findall(r'(\w+) (\d+)', line)
10 print(matches)    # [('number', '12345'), ('another', '42')]
```

If there are multiple capture groups then The returned list will consist of tuples.

Any Character

. matches any one character except newline.

For example: `##`

```
1 import re
2
3 strings = [
4     'abc',
5     'text: #q#',
6     'str: #a#',
7     'text #b# more text',
8     '#a and this? #c#',
9     '#a and this? # c#',
10    '#@#',
11    '#.#',
12    '# #',
13    '##'
14    '###'
15 ]
16
17 for s in strings:
18     print('str: ', s)
19     match = re.search(r'##', s)
20     if match:
21         print('match:', match.group(0))
```

If `re.DOTALL` is given newline will be also matched.

Match dot

```
1  import re
2
3  cases = [
4      "hello!",
5      "hello world.",
6      "hello. world",
7      ".",
8  ]
9
10 for case in cases:
11     print(case)
12     match = re.search(r'.', case)    # Match any character
13     if match:
14         print(match.group(0))
15
16 print("----")
17
18 for case in cases:
19     print(case)
20     match = re.search(r'\.', case)    # Match a dot
21     if match:
22         print(match.group(0))
23
24 print("----")
25
26 for case in cases:
27     print(case)
28     match = re.search(r'[.]', case)    # Match a dot
29     if match:
30         print(match.group(0))
```

Character classes

We would like to match any string that has any of the `#a#`, `#b#`, `#c#`, `#d#`, `#e#`, `#f#`, `#@#` or `#.#`

```

1  import re
2
3  strings = [
4      'abc',
5      'text: #q#',
6      'str: #a#',
7      'text #b# more text',
8      '#ab#',
9      '#@#',
10     '#.#',
11     '# #',
12     '##'
13     '###'
14 ]
15
16
17 for s in strings:
18     print('str: ', s)
19     match = re.search(r'#[abcdef@.]*', s)
20     if match:
21         print('match:', match.group(0))

```

```

1  r'#[abcdef@.]*'
2  r'[a-f@.]*'

```

Common character classes

- `\d` digit: `[0-9]` Use stand alone: `\d` or as part of a bigger character class: `[abc\d]`
- `\w` word character: `[0-9a-zA-Z_]`
- `\s` white space: `[\f\t\n\r]` form-feed, tab, newline, carriage return and SPACE

Negated character class

- `[^abc]` matches any one character that is not 'a', not 'b' and not 'c'.
- D not digit `[^\d]`
- W not word character `[^\w]`
- S not white space `[^\s]`

Optional character

Match the word **color** or the word **colour**

```
1  Regex: r'colou?r'
```

```
1  Input: color
2  Input: colour
3  Input: colouur
```

Regex 0 or more quantifier

Any line with two - -es with anything in between.

```
1  Regex: r'-.*- '
2  Input: "ab"
3  Input: "ab - cde"
4  Input: "ab - qqqrq -"
5  Input: "ab -- cde"
6  Input: "--"
```

Quantifiers

Quantifiers apply to the thing in front of them

```
1  r'ax*a'      # aa, axa, axxa, axxa, ...
2  r'ax+a'      #      axa, axxa, axxa, ...
3  r'ax?a'      # aa, axa
4  r'ax{2,4}a'   #      axxa, axxa, axxa
5  r'ax{3,}a'    #      axxa, axxa, ...
6  r'ax{17}a'    #      aaaaaaaaaaaaaaaaaa
```

*	0-
+	1-
?	0-1
	n-m
	n-
	n

Quantifiers limit

```
1  import re
2
3  strings = (
4      "axxxa",
5      "axxxxa",
6      "axxxxxa",
7  )
8
9  for text in strings:
10     match = re.search(r'ax{4}', text)
11     if match:
12         print("Match")
13         print(match.group(0))
14     else:
15         print("NOT Match")
```

Quantifiers on character classes

```
1  import re
2
3  strings = (
4      "-a-",
5      "-b-",
6      "-x-",
7      "-aa-",
8      "-ab-",
9      "--",
10 )
11
12 for line in strings:
13     match = re.search(r'-[abc]-', line)
14     if match:
15         print(line)
16 print('=====')
17
18 for line in strings:
19     match = re.search(r'-[abc]+-', line)
20     if match:
21         print(line)
22 print('=====')
23
24 for line in strings:
```

```
25     match = re.search(r'-[abc]*-', line)
26     if match:
27         print(line)
```

Greedy quantifiers

```
1  import re
2
3  match = re.search(r'xa*', 'xaaab')
4  print(match.group(0))
5
6  match = re.search(r'xa*', 'xabxaab')
7  print(match.group(0))
8
9  match = re.search(r'a*', 'xabxaab')
10 print(match.group(0))
11
12 match = re.search(r'a*', 'aaaxabxaab')
13 print(match.group(0))
```

They match 'xaa', 'xa' and '' respectively.

Minimal quantifiers

```
1  import re
2
3  match = re.search(r'a.*b', 'axbzb')
4  print(match.group(0))
5
6  match = re.search(r'a.*?b', 'axbzb')
7  print(match.group(0))
8
9
10 match = re.search(r'a.*b', 'axy121413413bq')
11 print(match.group(0))
12
13 match = re.search(r'a.*?b', 'axyb121413413q')
14 print(match.group(0))
```

Anchors

- A matches the beginning of the string
- Z matches the end of the string
- ^ matches the beginning of the row (see also re.MULTILINE)
- \$ matches the end of the row but will accept a trailing newline (see also re.MULTILINE)

```
1  import re
2
3  lines = [
4      "text with cat in the middle",
5      "cat with dog",
6      "dog with cat",
7  ]
8
9  for line in lines:
10     if re.search(r'cat', line):
11         print(line)
12
13
14  print("---")
15  for line in lines:
16     if re.search(r'^cat', line):
17         print(line)
18
19  print("---")
20  for line in lines:
21     if re.search(r'\Acat', line):
22         print(line)
23
24  print("---")
25  for line in lines:
26     if re.search(r'cat$', line):
27         print(line)
28
29  print("---")
30  for line in lines:
31     if re.search(r'cat\Z', line):
32         print(line)
```

```
1 text with cat in the middle
2 cat with dog
3 dog with cat
4 ---
5 cat with dog
6 ---
7 cat with dog
8 ---
9 dog with cat
10 ---
11 dog with cat
```

Anchors on both end

```
1 import re
2
3 strings = [
4     "123",
5     "hello 456 world",
6     "hello world",
7 ]
8
9 for line in strings:
10     if re.search(r'\d+', line):
11         print(line)
12
13 print('---')
14
15 for line in strings:
16     if re.search(r'^\d+$', line):
17         print(line)
18
19
20 print('---')
21
22 for line in strings:
23     if re.search(r'\A\d+\Z', line):
24         print(line)
```

```
1 123
2 hello 456 world
3 ---
4 123
5 ---
6 123
```

Match ISBN numbers

```
1

1 import re
2
3 strings = [
4     '99921-58-10-7',
5     '9971-5-0210-0',
6     '960-425-059-0',
7     '80-902734-1-6',
8     '85-359-0277-5',
9     '1-84356-028-3',
10    '0-684-84328-5',
11    '0-8044-2957-X',
12    '0-85131-041-9',
13    '0-943396-04-2',
14    '0-9752298-0-X',
15
16    '0-975229-1-X',
17    '0-9752298-10-X',
18    '0-9752298-0-Y',
19    '910975229-0-X',
20    '-----',
21    '0000000000000',
22 ]
23 for isbn in strings:
24     print(isbn)
25
26     if (re.search(r'^[\dX-]{13}$', isbn)):
27         print("match 1")
28
29     if (re.search(r'^\d{1,5}-\d{1,7}-\d{1,5}-[\dX]$', isbn) and len(isbn) == 13):
30         print("match 2")
```

Matching a section

```
1 import re
2
3 text = "This is <a string> with some sections <marked> with special characters"
4
5 m = re.search(r'<.*>', text)
6 if m:
7     print(m.group(0))
```

Matching a section - minimal

```
1 import re
2
3 text = "This is <a string> with some sections <marked> with special characters"
4
5 m = re.search(r'<.*?>', text)
6 if m:
7     print(m.group(0))
```

Matching a section negated character class

```
1 import re
2
3 text = "This is <a string> with some sections <marked> with special characters"
4
5 m = re.search(r'<[^>]*>', text)
6 if m:
7     print(m.group(0))
```

DOTALL S (single line)

if re.DOTALL is given, . will match any character. Including newlines.

```
1  import re
2
3  line = 'Before <div>content</div> After'
4
5  text = '''
6  Before
7  <div>
8  content
9  </div>
10 After
11 '''
12
13 if (re.search(r'<div>.*</div>', line)):
14     print('line');
15 if (re.search(r'<div>.*</div>', text)):
16     print('text');
17
18 print('-' * 10)
19
20 if (re.search(r'<div>.*</div>', line, re.DOTALL)):
21     print('line');
22 if (re.search(r'<div>.*</div>', text, re.DOTALL)):
23     print('text');
```

MULTILINE M

if re.MULTILINE is given, ^ will match beginning of line and \$ will match end of line

```
1  import re
2
3  line = 'Start    blabla End'
4
5  text = '''
6  prefix
7  Start
8  blabla
9  End
10 postfix
11 '''
12
13 regex = r'^Start[\d\D]*End$'
14 m = re.search(regex, line)
```

```

15 if (m):
16     print('line')
17
18 m = re.search(regex, text)
19 if (m):
20     print('text')
21
22 print('-' * 10)
23
24 m = re.search(regex, line, re.MULTILINE)

3  foo@bar.com=email
```

Exercises: Regexes part 1

Pick up a file with some text in it. Write a script (one for each item) that prints out every line from the file

that matches the requirement. You can use the script at the end of the page as a starting point but you will have to change it!

- has a 'q'
- starts with a 'q'
- has 'th'
- has an 'q' or a 'Q'

- has a '*' in it
- starts with an 'q' or an 'Q'
- has both 'a' and 'e' in it
- has an 'a' and somewhere later an 'e'
- does not have an 'a'
- does not have an 'a' nor 'e'
- has an 'a' but not 'e'
- has at least 2 consecutive vowels (a,e,i,o,u) like in the word "bear"
- has at least 3 vowels
- has at least 6 characters
- has at exactly 6 characters
- all the words with either 'Bar' or 'Baz' in them
- all the rows with either 'apple pie' or 'banana pie' in them
- for each row print if it was apple or banana pie?
- Bonus: Print if the same word appears twice in the same line
- Bonus: has a double character (e.g. 'oo')

```

1  import sys
2  import re
3
4  if len(sys.argv) != 2:
5      print("Usage:", sys.argv[0], "FILE")
6      exit()
7
8  filename = sys.argv[1]
9  with open(filename, 'r') as fh:
10     for line in fh:
11         print(line, end=" ")
12
13         match = re.search(r'REGEX1', line)
14         if match:
15             print("    Matching 1", match.group(0))
16
17         match = re.search(r'REGEX2', line)
18         if match:
19             print("    Matching 2", match.group(0))

```

Exercise: Regexes part 2

Write functions that returns true if the given value is a

- Hexadecimal number
- Octal number
- Binary number

Write a function that given a string it return true if the string is a number.
As there might be several definitions of what is the number create several solutions one for each definition:

- Non negative integer.
- Integer. (Will you also allow + in front of the number or only - ?
- Real number. (Do you allow .3 ? What about 2. ?
- In scientific notation. (something like this: 2.123e4)

```
1 23
2 2.3
3 2.3.4
4 2.4e3
5 abc
```

Exercise: Sort SNMP numbers

Given a file with SNMP numbers (one number on every line)
print them in sorted order comparing the first number of
each SNMP number first.

If they are equal then comparing the second number, etc...

input:

```
1 1.2.7.6
2 4.5.7.23
3 1.2.7
4 1.12.23
5 2.3.5.7.10.8.9
6 1.2.7.5
```

output:

```
1 1.2.7
2 1.2.7.5
3 1.2.7.6
4 1.12.23
5 2.3.5.7.10.8.9
6 4.5.7.23
```

Exercise: parse hours log file and give report

The log file looks like this

```
1 09:20 Introduction
2 11:00 Exercises
3 11:15 Break
4 11:35 Numbers and strings

Exercise: Parse ini file

An ini file has sections starting by the name of the section in square brackets and within each section there are key = value pairs with optional spaces around the “=” sign.

The keys can only contain letters, numbers, underscore or dash.

In addition there can be empty lines and lines starting with # which are comments.

Given a filename, generate a 2 dimensional hash and then print it out.

Example ini file:

```
1  # comment
2  [alpha]
3
4  base  = moon
5  ship= alpha 3
6
7  [earth]
8      # ?
9  base=London
10 ship=  x-wing
```

If you print it, it should look like this (except of the nice formatting).

```
1  {
2      'alpha': {
3          'base': 'moon',
4          'ship': 'alpha 3'
5      },
6      'earth': {
7          'base': 'London',
8          'ship': 'x-wing'
9      }
10 }
```

Exercise: Replace Python

```
1  Replace all occurrences of Python or python by Java ...
2  ... but avoid replacing Monty Python.
```

Exercise: Extract phone numbers

- 1 Given a text message fetch all the phone numbers:
- 2 Fetch numbers that look like 09-1234567
- 3 then also fetch +972-2-1234567
- 4 and maybe also 09-123-4567
- 5 This 123 is not a phone number.

Solution: Sort SNMP numbers

```

1  import sys
2
3  def process(filename):
4      snmps = []
5      with open(filename) as fh:
6          for row in fh:
7              snmps.append({
8                  'orig': row.rstrip(),
9              })
10     #print(snmps)
11
12     max_number_of_parts = 0
13     max_number_of_digits = 0
14     for snmp in snmps:
15         snmp['split'] = snmp['orig'].split('.')
16         max_number_of_parts = max(max_number_of_parts, len(snmp['split']))
17         for part in snmp['split']:
18             max_number_of_digits = max(max_number_of_digits, len(part))
19
20     padding = "{:0" + str(max_number_of_digits) + "}"
21     #print(padding)
22     for snmp in snmps:
23         padded = []
24         padded_split = snmp['split'] + ['0'] * (max_number_of_parts - len(snmp['split']\
25 ']))
26
27         for part in padded_split:
28             padded.append(padding.format( int(part)))
29         snmp['padded'] = padded
30         snmp['joined'] = '.'.join(padded)
31
32
33     #print(snmps)
34     #print(max_number_of_parts)

```

```

35     #print(max_number_of_digits)
36
37     snmps.sort(key = lambda e: e['joined'])
38     sorted_snmps = []
39     for snmp in snmps:
40         sorted_snmps.append( snmp['orig'] )
41     for snmp in sorted_snmps:
42         print(snmp)
43
44     # get the max number of all the snmp parts
45     # make each snmp the same length
46     # pad each part to that length with leading 0s
47
48     if len(sys.argv) < 2:
49         exit("Usage: {} FILENAME".format(sys.argv[0]))
50     process(sys.argv[1])

```

Solution: parse hours log file and give report

```

1  import sys
2
3
4  if len(sys.argv) < 2:
5      exit("Usage: {} FILENAME".format(sys.argv[0]))
6
7
8
9  data = {}
10
11 def read_file(filename):

Regular Expressions Cheat sheet

Expression	Meaning
a	Just an 'a' character
.	any character except new-line
[bgh.]	one of the chars listed in the character class b,g,h or .
[b-h]	The same as [bcdefgh]
[a-z]	Lower case letters
[b-]	The letter b or -
[^bx]	Anything except b or x
\w	Word characters: [a-zA-Z0-9_]
\d	Digits: [0-9]
\s	[\f\t\n\r] form-feed, tab, newline, carriage return and SPACE
W	[^\w]
D	[^\d]
S	[^\s]
a*	0-infinite 'a' characters
a+	1-infinite 'a' characters
a?	0-1 'a' characters

a	n-m 'a' characters
()	Grouping and capturing
\1, \2	Capture buffers
^ \$	Beginning and end of string anchors

24     #     fh.write(good_json)
25
26 data = json.loads(good_json)
27 print(data)

```

Raw string or escape

Let's try to check if a string contains a back-slash?

```

1  import re
2
3  txt = 'text with slash \ and more text'
4  print(txt)           # text with slash \ and more text
5
6  # m0 = re.search('\\', txt)
7  # SyntaxError: EOL while scanning string literal
8
9  # m0 = re.search('\\\\', txt)
10 # Exception: sre_constants.error: bogus escape (end of line)

```

```

11     # because the regex engine does not know what to do with a single \
12
13 m1 = re.search('\\', txt)
14 if m1:
15     print('m1')    # m1
16
17 m2 = re.search(r'\\', txt)
18 if m2:
19     print('m2')    # m2

```

Remove spaces regex

This is not necessary as we can use `rstrip`, `lstrip`, and `replace`.

```

1  import re
2
3  line = "  ab cd  "
4
5  res = re.sub(r'^\s+', '', line) # leading
6  print(f"{'res'}")
7
8  res = re.sub(r'\s+$', '', line) # trailing
9  print(f"{'res'}")

```

both ends:

```

1  re.sub(r'\s*(.*?)\s*$', r'\1', line) # " abc " => "abc " because of the greediness

1  re.sub(r'^\s*(.*?)\s*$', '\1', line) # " abc " => "abc" minimal match

```

Regex Unicode

Python 3.8 required

```

1  print("\N{GREEK CAPITAL LETTER DELTA}")
2
3  print("\u05E9")
4  print("\u05DC")
5  print("\u05D5")
6  print("\u05DD")
7  print("\u262E")
8  print("\u1F426")    # "bird"
9
10 print("\u05E9\u05DC\u05D5\u05DD \u262E")

```

```

1  Hello World!
2  Szia Világ!
3  סתם! סתם

```

```

1  import re
2
3  filename = "mixed.txt"
4
5  with open(filename) as fh:
6      lines = fh.readlines()
7  for line in lines:
8      if re.search('\N{IN HEBREW}', line):
9          print(line)

```

Anchors Other example

```

1  import re
2
3  strings = [
4      "123-XYZ-456",
5      "a 123-XYZ-456 b",
6      "a 123-XYZ-456",
7      "123-XYZ-456 b",
8      "123-XYZ-456\n",
9  ]
10
11 regexes = [
12     r'\d{3}-\w+-\d{3}',
13     r'^\d{3}-\w+-\d{3}',

```

```
14     r'\d{3}-\w+-\d{3}$',
15     r'^\d{3}-\w+-\d{3}$',
16     r'^\d{3}-\w+-\d{3}\Z',
17     r'\A\d{3}-\w+-\d{3}\Z',
18 ]
19
20 for r in regexes:
21     print(r)
22     for s in strings:
23         #print(r, s)
24         if (re.search(r, s)):
25             print('    ', s)
26     print('-' * 10)
```

OS path

```
1  import os
2
3  os.path.basename(path_to_thing)
4  os.path.dirname(path_to_thing)
5  os.path.abspath(path_to_file)
6
7  os.path.exists(path_to_file)
8  os.path.isdir(path_to_thing)
9
10 os.path.expanduser('~')
```

Traverse directory tree - list directories recursively

```
1  import os
2  import sys
3
4  if len(sys.argv) != 2:
5      exit("Usage: {} PATH_TO_DIRECTORY".format(sys.argv[0]))
6
7  root = sys.argv[1]
8
9  for dirname, dirs, files in os.walk(root):
10     #print(dirname)      # relative path (from cwd) to the directory being processed
11     #print(dirs)         # list of subdirectories in the currently processed directory
12     #print(files)        # list of files in the currently processed directory
13
14     for filename in files:
15         print(os.path.join(dirname, filename))    # relative path to the "current" fi\
16 le
```

os.path.join

```
1  import os
2
3  path = os.path.join('home', 'foo', 'work')
4  print(path)    # home/foo/work
```

Directory listing

```
1  import os
2  import sys
3
4  if len(sys.argv) != 2:
5      exit("Usage: {} directory".format(sys.argv[0]))
6
7  path = sys.argv[1]
8  files = os.listdir(path)
9  for name in files:
10     print(name)
11     print(os.path.join(path, name))
```

expanduser - handle tilde ~

```
1 import os
2
3 print( os.path.expanduser("~") )
4 print( os.path.expanduser("~/work") )
5 print( os.path.expanduser("~/other") )
6 print( os.path.expanduser("some/other/dir/no/expansion") )
```

Listing specific files using glob

```
1 import glob
2
3 files = glob.glob("*.py")
4 print(files)
5
6 files = glob.glob("/usr/bin/*.sh")
7 print(files)
```

External command with system

```
1 import os
2
3 command = 'ls -l'
4
5 os.system(command)
```

If you wanted to list the content of a directory in an os independent way you'd use `os.listdir('.')` or you could use the `glob.glob("*.py")` function to have a subset of files.

subprocess

Run external command and capture the output

```
1  import time
2  import sys
3
4  for i in range(3):
5      print("OUT {}".format(i))
6      print("ERR {}".format(i), file=sys.stderr)
7      time.sleep(1)
```

```
1  import subprocess
2  import sys
3
4  command = [sys.executable, 'slow.py']
5
6  proc = subprocess.Popen(command,
7      stdout = subprocess.PIPE,
8      stderr = subprocess.PIPE,
9  )
10
11 out,err = proc.communicate() # runs the code
12
13 # out and err are two strings
14
15 print('exit code:', proc.returncode)
16
17 print('out:')
18 for line in out.decode('utf8').split('\n'):
19     print(line)
20
21 print('err:')
22 for line in err.decode('utf8').split('\n'):
23     print(line)
```

In this example `p` is an instance of the `subprocess.PIPE` class. The command is executed when the object is created.

subprocess in the background

```
1  import subprocess
2  import sys
3  import time
4
5
6  proc = subprocess.Popen([sys.executable, 'slow.py'],
7      stdout = subprocess.PIPE,
8      stderr = subprocess.PIPE,
9  )
10
11  #out, err = proc.communicate() # this is when the code starts executing
12  #print(out)
13  #print(err)
14
15  timeout = 6
16  while True:
17      poll = proc.poll()
18      print(poll)
19      time.sleep(0.5)
20      timeout -= 0.5
21      if timeout <= 0:
22          break
23      if poll is not None:
24          break
25
26  print("Final: {}".format(poll))
27  if poll is None:
28      pass
29  else:
30      out, err = proc.communicate()
31      print(out)
32      print(err)
```

Accessing the system environment variables from Python

```
1 import os
2
3 print(os.environ['HOME']) # /Users/gabor
4 print(os.environ.get('HOME')) # /Users/gabor
5
6 for k in os.environ.keys():
7     print("{:30} {}".format(k, os.environ[k]))
```

`os.environ` is a dictionary where the keys are the environment variables and the values are, well, the values.

Set env and run command

```
1 import os
2
3 os.system("echo hello")
4 os.system("echo $HOME")
5
6 os.system("echo Before $MY_TEST")
7 os.environ['MY_TEST'] = 'qqrq'
8 os.system("echo After $MY_TEST")
```

We can change the environment variables and that change will be visible in subprocesses, but once we exit from our Python program, the change will not persist.

shutil

```
1 import shutil
2
3 shutil.copy(source, dest)
4 shutil.copytree(source, dest)
5 shutil.move(source, dest)
6 shutil.rmtree(path)
```

time

```
1 import time
2
3 print(time.time())      # 1351178170.85
4
5 print(time.timezone)    # 7200 = 2*60*60 (GMT + 2)
6 print(time.daylight)    # 1 (DST or Daylight Saving Time)
7
8 print(time.gmtime())    # time.struct_time
9     # time.struct_time(tm_year=2012, tm_mon=10, tm_mday=25,
10     # tm_hour=17, tm_min=25, tm_sec=34, tm_wday=3, tm_yday=299, tm_isdst=0)
11
12 t = time.gmtime()
13 print(t.tm_year) # 2012
14
15 print(time.strftime('%Y-%m-%d %H:%M:%S')) # with optional timestamp
```

sleep in Python

```
1 import time
2
3 start = time.time()
4 print("hello " + str(start))
5
6 time.sleep(3.5)
7
8 end = time.time()
9 print("world " + str(end))
10 print("Elapsed time:" + str(end-start))
```

```
1 hello 1475217162.472256
2 world 1475217165.973437
3 Elapsed time:3.501181125640869
```

timer

More time-related examples.

```
1 import random
2 import time
3
4 # https://docs.python.org/3/library/time.html#time.struct\_time
5
6 print(time.time())      # time since the epoch in seconds
7 print(time.asctime())   # current local time in human-readable format
8 print(time.strftime("%Y-%m-%d %H:%M:%S")) # create your own human-readable format
9
10 print(time.gmtime(0))   # epoch
11 print(time.asctime(time.gmtime(0))) # epoch in human-readable format
12
13 print(time.localtime()) # local time now
14 print(time.gmtime())    # time in London
15
16
17
18 print(time.process_time())
19 print(time.process_time_ns())
20
21 s = time.perf_counter()
22 ps = time.process_time()
23 print(time.monotonic())
24 time.sleep(0.1)
25 print(time.monotonic())
26 e = time.perf_counter()
27 for _ in range(100000):
28     random.random()
29 pe = time.process_time()
30 print(s)
31 print(e)
32 print(e-s)
33 print(pe-ps)
```

```

34
35 # print(time.get_clock_info('monotonic'))

```

Current date and time datetime now

```

1  import datetime
2
3  now = datetime.datetime.now()
4  print(now)           # 2015-07-02 16:28:01.762244
5  print(type(now))     # <type 'datetime.datetime'>
6
7  print(now.year)      # 2015
8  print(now.month)     # 7
9  print(now.day)       # 2
10 print(now.hour)      # 16
11 print(now.minute)    # 28
12 print(now.second)    # 1
13 print(now.microsecond) # 762244
14
15 print(now.strftime("%Y%m%d-%H%M%S-%f")) # 20150702-162801-762244
16 print(now.strftime("%B %b %a %A"))     # July Jul Thu Thursday
17 print(now.strftime("%c"))               # Thu Jul 2 16:28:01 2015

```

Converting string to datetime

```

1  import datetime
2
3  usa_date_format = "%m/%d/%Y" # MM/DD/YYYY
4  world_date_format = "%d/%m/%Y" # DD/MM/YYYY
5  other_date_format = "%Y/%m/%d" # YYYY/MM/DD
6
7
8  d = "2012-12-19"
9  some_day = datetime.datetime.strptime(d, '%Y-%m-%d') # YYYY-MM-DD
10 print(some_day)           # 2012-12-19
11 print(type(some_day))     # <type 'datetime.datetime'>
12
13 t = "2013-11-04 11:23:45" # YYYY-MM-DD HH:MM:SS
14 some_time = datetime.datetime.strptime(t, '%Y-%m-%d %H:%M:%S')
15 print(type(some_time))    # <type 'datetime.date'>
16 print(some_time)          # 2013-11-04
17 print(some_time.minute)   # 23

```

datetime arithmetics

```

1  import datetime
2
3  t1 = "2013-12-29T11:23:45"
4  t2 = "2014-01-02T10:19:49"
5  dt1 = datetime.datetime.strptime(t1, '%Y-%m-%dT%H:%M:%S')
6  dt2 = datetime.datetime.strptime(t2, '%Y-%m-%dT%H:%M:%S')
7  print(dt1)          # 2013-12-29 11:23:45
8  print(dt2)          # 2014-01-02 10:19:49
9
10 d = dt2-dt1
11 print(d)             # 3 days, 22:56:04
12 print(type(d))       # <type 'datetime.timedelta'>
13 print(d.total_seconds()) # 341764.0
14
15 nd = dt1 + datetime.timedelta(days = 3)
16 print(nd)            # 2014-01-01 11:23:45

```

Rounding datetime object to nearest second

```

1  import datetime
2
3  d = datetime.datetime.now()
4  x = d - datetime.timedelta(microseconds=d.microsecond)
5  print(d) # 2019-11-01 07:11:19.930974
6  print(x) # 2019-11-01 07:11:19

```

Signals and Python

- [man 7 signal](#)⁸⁹ (on Linux)
- Unix: kill PID, kill -9 PID, Ctrl-C, Ctrl-Z
- os.kill
- [signal](#)⁹⁰

Sending Signal

⁸⁹<http://man7.org/linux/man-pages/man7/signal.7.html>

⁹⁰<https://docs.python.org/3/library/signal.html>

```
1 import signal
2 import os
3
4 print("before")
5 os.kill(os.getpid(), signal.SIGUSR1)
6 print("after")
```

```
1 before
2 User defined signal 1: 30
```

Catching Signal

```
1 import signal
2 import os
3
4 def handler(signum, frame):
5     print('Signal handler called with signal', signum)
6
7 signal.signal(signal.SIGUSR1, handler)
8
9 print("before")
10 os.kill(os.getpid(), signal.SIGUSR1)
11 print("after")
```

```
1 before
2 ('Signal handler called with signal', 30)
3 after
```

Catching Ctrl-C on Unix

```
1 username = input('Username:')
2 print(username)
```

```
1 $ python ctrl_c.py
```

```
1  Username: ^CTraceback (most recent call last):
2    File "ctrl_c.py", line 3, in <module>
3        username = input('Username:')
4  KeyboardInterrupt

1  import signal
2
3  def handler(signum, frame):
4      print('Signal handler called with signal', signum)
5
6  signal.signal(signal.SIGINT, handler)
7
8  username = input('Username:')
9  print(username)
```

- Cannot stop using Ctrl-C !
- Ctrl-Z and then kill %1
- kill PID

Catching Ctrl-C on Unix confirm

```
1  import signal
2  import time
3
4  def handler(signum, frame):
5      answer = input('We are almost done. Do you really want to exit? [yes]:')
6      if answer == 'yes':
7          print('bye')
8          exit()
9      print("Then let's keep running")
10
11 signal.signal(signal.SIGINT, handler)
12
13 for _ in range(10):
14     time.sleep(5)
```

Alarm signal and timeouts

```
1  import signal
2
3  class MyTimeout(Exception):
4      pass
5
6  def handler(signum, frame):
7      print('Signal handler called with signal', signum)
8      raise MyTimeout
9
10 try:
11     signal.signal(signal.SIGALRM, handler)
12     signal.alarm(5)
13     number = input("Divide by (5 sec):")
14     signal.alarm(0)
15     print(42/int(number))
16 except MyTimeout:
17     print('timeout')
18 except Exception as e:
19     print(e)
20     #raise
21
22 print("Still working")
```

deep copy list

```
1  a = [
2      {
3          'name': 'Joe',
4          'email': 'joe@examples.com',
5      },
6      {
7          'name': 'Mary',
8          'email': 'mary@examples.com',
9      },
10 ]
11
12
13 b = a
14 a[0]['phone'] = '1234'
15 a[0]['name'] = 'Jane'
16 a.append({
17     'name': 'George'
```

```
18 })
19
20 print(a)
21 print(b)
```

```
1  [{'name': 'Jane', 'email': 'joe@examples.com', 'phone': '1234'}, {'name': 'Mary', 'e\
2  mail': 'mary@examples.com'}, {'name': 'George'}]

17     'name': 'George'
18 })
19
20 print(a)
21 print(b)
```

```
1  [{'name': 'Jane', 'email': 'joe@examples.com', 'phone': '1234'}, {'name': 'Mary', 'e\
2  mail': 'mary@examples.com'}, {'name': 'George'}]
3  [{'name': 'Jane', 'email': 'joe@examples.com', 'phone': '1234'}, {'name': 'Mary', 'e\
4  mail': 'mary@examples.com'}]
```

```
1  from copy import deepcopy
2
3  a = [
4      {
5          'name': 'Joe',
6          'email': 'joe@examples.com',
7      },
8      {
9          'name': 'Mary',
10         'email': 'mary@examples.com',
11     },
12 ]
13
14
15 b = deepcopy(a)
16 a[0]['phone'] = '1234'
17 a[0]['name'] = 'Jane'
18 a.append({
19     'name': 'George'
20 })
21
22 print(a)
23 print(b)
```

```
1  [{ 'name': 'Jane', 'email': 'joe@examples.com', 'phone': '1234' }, { 'name': 'Mary', 'e\
2  mail': 'mary@examples.com' }, { 'name': 'George' }]
3  [{ 'name': 'Joe', 'email': 'joe@examples.com' }, { 'name': 'Mary', 'email': 'mary@examp\
4  les.com' }]
```

deep copy dictionary

```
1  a = {
2      'name': 'Foo Bar',
3      'grades': {
4          'math': 70,
5          'art' : 100,
6      },
7      'friends': ['Mary', 'John', 'Jane', 'George'],
8  }
9
10 b = a
```

```

11 a['grades']['math'] = 90
12 a['email'] = 'foo@bar.com'
13 print(a)
14 print(b)

```

```

1 {'name': 'Foo Bar', 'grades': {'math': 90, 'art': 100}, 'friends': ['Mary', 'John', \
2 'Jane', 'George'], 'email': 'foo@bar.com'}
3 {'name': 'Foo Bar', 'grades': {'math': 90, 'art': 100}, 'friends': ['Mary', 'John', \
4 'Jane', 'George'], 'email': 'foo@bar.com'}

```

- `deepcopy`⁹¹

```

1 from copy import deepcopy
2
3 a = {
4     'name': 'Foo Bar',
5     'grades': {
6         'math': 70,
7         'art': 100,
8     },
9     'friends': ['Mary', 'John', 'Jane', 'George'],
10 }
11
12 b = deepcopy(a)
13 a['grades']['math'] = 90
14 a['email'] = 'foo@bar.com'
15 print(a)
16 print(b)

```

```

1 {'name': 'Foo Bar', 'grades': {'math': 90, 'art': 100}, 'friends': ['Mary', 'John', \
2 'Jane', 'George'], 'email': 'foo@bar.com'}
3 {'name': 'Foo Bar', 'grades': {'math': 70, 'art': 100}, 'friends': ['Mary', 'John', \
4 'Jane', 'George']}

```

Exercise: Catching Ctrl-C on Unix 2nd time

- When Ctrl-C is pressed display: “In order to really kill the application press Ctrl-C again” and keep running. If the user presses Ctrl-C again, then let it die.
- Improve the previous that if 5 sec within the first Ctrl-C there is no 2nd Ctrl-C then any further Ctrl-C will trigger the above message again.

⁹¹<https://docs.python.org/library/copy.html#copy.deepcopy>

Exercise: Signals

- What signal is sent when you run **kill PID**?
- Write a script that will disable the **kill PID** for your process. How can you kill it then?
- What signal is sent when we press Ctrl-Z ?

Ctrl-z

```
1 import signal
2 import os
3
4 print(os.getpid())
5
6 username = input('Username:')
7 print(username)
```

```
1 kill PID
```

```
1 import signal
2 import os
3
4 print(os.getpid())
5
6 def handler(signum, frame):
7     print('Signal handler called with signal', signum)
8
9 signal.signal(signal.SIGTERM, handler)
10
11 username = input('Username:')
12 print(username)
```

JSON

JSON - JavaScript Object Notation

JSON⁹² is basically the data format used by JavaScript. Because its universal availability it became the de-facto standard for data communication between many different languages. Most dynamic languages have an fairly good mapping between JSON and their own data structures. Lists and dictionaries in the case of Python.

Documentation of the [Python json library](http://docs.python.org/library/json.html)⁹³.

```
1  {"lname": "Bar", "email": null, "fname": "Foo", "children": ["Moo", "Koo", "Roo"]}
```

dumps

```
1  import json
2
3  a = {
4      "fname" : 'Foo',
5      "lname" : 'Bar',
6      "email" : None,
7      "children" : [
8          "Moo",
9          "Koo",
10         "Roo"
11     ]
12 }
13 print(a)
14
15 json_str = json.dumps(a)
16 print(json_str)
17
18 with open('data.json', 'w') as fh:
19     fh.write(json_str)
```

⁹²<http://www.json.org/>

⁹³<http://docs.python.org/library/json.html>

```
1  {'lname': 'Bar', 'email': None, 'fname': 'Foo',  
2   'children': ['Moo', 'Koo', 'Roo']}  
3  
4  {"lname": "Bar", "email": null, "fname": "Foo",  
5   "children": ["Moo", "Koo", "Roo"]}
```

(lines were broken for readability on the slides)

`dumps` can be used to take a Python data structure and generate a string in JSON format. That string can then be saved in a file, inserted in a database, or sent over the wire.

loads

```
1  import json  
2  
3  with open('examples/json/data.json') as fh:  
4      json_str = fh.read()  
5  
6  print(json_str)  
7  b = json.loads(json_str)  
8  print(b)  
  
1  {"lname": "Bar", "email": null, "fname": "Foo",  
2   "children": ["Moo", "Koo", "Roo"]}  
3  
4  {'lname': u'Bar', u'email': None, u'fname': u'Foo',  
5   u'children': [u'Moo', u'Koo', u'Roo']}
```

`u` is the Unicode prefix used in Python 2. In Python 3 it won't appear as Unicode is the default there.

dump

```
1 import json
2
3 a = {
4     "fname" : 'Foo',
5     "lname" : 'Bar',
6     "email" : None,
7     "children" : [
8         "Moo",
9         "Koo",
10        "Roo"
11    ]
12 }
13
14 print(a)
15
16 with open('data.json', 'w') as fh:
17     json.dump(a, fh)
```

```
1 {'lname': 'Bar', 'email': None, 'fname': 'Foo',
2   'children': ['Moo', 'Koo', 'Roo']}
3
4 {"lname": "Bar", "email": null, "fname": "Foo",
5  "children": ["Moo", "Koo", "Roo"]}
```

(lines were broken for readability on the slides)

As a special case **dump** will save the string in a file or in other stream.

load

```
1 import json
2
3 with open('examples/json/data.json', 'r') as fh:
4     a = json.load(fh)
5 print(a)
```

```
1 {'lname': u'Bar', u'email': None, u'fname': u'Foo',
2   u'children': [u'Moo', u'Koo', u'Roo']}
```

Round trip

```
1  import json
2  import os
3  import time
4
5  data = {}
6  filename = 'mydata.json'
7
8  if os.path.exists(filename):
9      with open(filename) as fh:
10         json_str = fh.read()
11         print(json_str)
12         data = json.loads(json_str)
13
14  data['name'] = 'Foo Bar'
15  data['time'] = time.time()
16
17
18  with open(filename, 'w') as fh:
19      json_str = json.dumps(data)
20      fh.write(json_str)
```

Pretty print JSON

```
1  import json
2
3  data = {
4      "name" : "Foo Bar",
5      "grades" : [23, 47, 99, 11],
6      "children" : {
7          "Peti Bar" : {
8              "email": "peti@bar.com",
9          },
10         "Jenny Bar" : {
11             "phone": "12345",
12         },
13     }
14 }
15
16 print(data)
17 print(json.dumps(data))
18 print(json.dumps(data, indent=4, separators=(',', ': ')))
```

```
1  {'name': 'Foo Bar', 'grades': [23, 47, 99, 11], 'children': {'Peti Bar': {'email': '\
2  peti@bar.com'}, 'Jenny Bar': {'phone': '12345'}}}
3  {"name": "Foo Bar", "grades": [23, 47, 99, 11], "children": {"Peti Bar": {"email": "\
4  peti@bar.com"}, "Jenny Bar": {"phone": "12345"}}}
5  {
6      "name": "Foo Bar",
7      "grades": [
8          23,
9          47,
10         99,
11         11
12     ],
13     "children": {
14         "Peti Bar": {
15             "email": "peti@bar.com"
16         },
17         "Jenny Bar": {
18             "phone": "12345"
19         }
20     }
21 }
```

Sort keys in JSON

```
1  import json
2
3  data = {
4      "name" : "Foo Bar",
5      "grades" : [23, 47, 99, 11],
6      "children" : {
7          "Peti Bar" : {
8              "email": "peti@bar.com",
9          },
10         "Jenny Bar" : {
11             "phone": "12345",
12         },
13     }
14 }
15
16 print(json.dumps(data, sort_keys=True, indent=4, separators=(',', ': ')))
```

```
1  {
2      "children": {
3          "Jenny Bar": {
4              "phone": "12345"
5          },
6          "Peti Bar": {
7              "email": "peti@bar.com"
8          }
9      },
10     "grades": [
11         23,
12         47,
13         99,
14         11
15     ],
16     "name": "Foo Bar"
17 }
```

Set order of keys in JSON - OrderedDict

```
1  from collections import OrderedDict
2
3  d = {}
4  d['a'] = 1
5  d['b'] = 2
6  d['c'] = 3
7  d['d'] = 4
8  print(d)
9
10 planned_order = ('b', 'c', 'd', 'a')
11 e = OrderedDict(sorted(d.items(), key=lambda x: planned_order.index(x[0])))
12 print(e)
13
14 print('-----')
15 # Create index to value mapping dictionary from a list of values
16 planned_order = ('b', 'c', 'd', 'a')
17 plan = dict(zip(planned_order, range(len(planned_order))))
18 print(plan)
19
20 f = OrderedDict(sorted(d.items(), key=lambda x: plan[x[0]]))
21 print(f)
```

```

1  {'a': 1, 'b': 2, 'c': 3, 'd': 4}
2  OrderedDict([('b', 2), ('c', 3), ('d', 4), ('a', 1)])
3  -----
4  {'b': 0, 'c': 1, 'd': 2, 'a': 3}
5  OrderedDict([('b', 2), ('c', 3), ('d', 4), ('a', 1)])

```

Exercise: Counter in JSON

Write a script that will provide several counters. The user can provide an argument on the command line and the script will increment and display that counter. Keep the current values of the counters in a single JSON file. The script should behave like this:

```

1  $ python counter.py foo
2  1
3
4  $ python counter.py foo
5  2
6
7  $ python counter.py bar
8  1
9
10 $ python counter.py foo
11 3

```

Exercise: Phone book

Write a script that acts as a phonebook. As “database” use a file in JSON format.

```

1  $ python phone.py Foo 123
2  Foo added
3
4  $ python phone.py Bar
5  Bar is not in the phnebook
6
7  $ python phone.py Bar 456
8  Bar added
9
10 $ python phone.py Bar
11 456

```

```
12
13 $ python phone.py Foo
14 123
```

Can it handle changes in phone numbers?
Can it remove a name from the “database”?

Exercise: Processes

Write a program that will do “some work” that can be run in parallel and collect the data. Make the code work in a single process by default and allow the user to pass a number that will be the number of child processes to be used. When the child process exits it should save the results in a file and the parent process should read them in.

The “some work” can be accessing 10-20 machines using “ssh machine uptime” and creating a report from the results.

It can be fetching 10-20 URLs and reporting the size of each page.

It can be any other network intensive task.

Measure the time in both cases

Solution: Counter in JSON

```
1  import json
2  import sys
3  import os
4
5  filename = 'counter.json'
6
7  if len(sys.argv) != 2:
8      print("Usage: " + sys.argv[0] + " COUNTER")
9      exit()
10
11 counter = {}
12
13 if os.path.exists(filename):
14     with open(filename) as fh:
15         json_str = fh.read()
16         counter = json.loads(json_str)
17
```

```
18 name = sys.argv[1]
19 if name in counter:
20     counter[name] += 1
21 else:
22     counter[name] = 1
23
24 print(counter[name])
25
26
27 with open(filename, 'w') as fh:
28     json_str = json.dumps(counter)
29     fh.write(json_str)
```

Solution: Phone book

```
1 import sys
2 import json
3 import os
4
5 def main():
6     filename = 'phonebook.json'
7     phonebook = {}
8     if os.path.exists(filename):
9         with open(filename) as fh:
10             json_str = fh.read()
11             phonebook = json.loads(json_str)
12
13     if len(sys.argv) == 2:
14         name = sys.argv[1]
15         if name in phonebook:
16             print(phonebook[name])
17         else:
18             print("{} is not in the phonebook".format(name))
19         return
20
21     if len(sys.argv) == 3:
22         name = sys.argv[1]
23         phone = sys.argv[2]
24         phonebook[name] = phone
25         with open(filename, 'w') as fh:
26             json_str = json.dumps(phonebook)
27             fh.write(json_str)
```

```
28         return
29
30     print("Invalid number of parameters")
31     print("Usage: {} username [phone]".format(sys.argv[0]))
32
33 if __name__ == '__main__':
34     main()
```

Command line arguments with argparse

Modules to handle the command line

You would like to allow the user to pass arguments on the command line. For example:

```
1 myprog.py --machine server_name --test name --verbose --debug
2 myprog.py -v -d
3 myprog.py -vd
4 myprog.py file1 file2 file3
```

- [sys.argv](http://docs.python.org/library/sys.html)⁹⁴ manual parsing?
- [optparse](http://docs.python.org/library/optparse.html)⁹⁵ (deprecated)
- [argparse](http://docs.python.org/library/argparse.html)⁹⁶

argparse

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('--name')      # optional named parameter that requires a value
5 parser.add_argument('--name', help="Some description")
6
7 parser.add_argument('--max', help='max number of something', type=int) # check and co\
8 nvert to integer
9 parser.add_argument('--verbose', action='store_true') # "flag" no value is expected
10
11 parser.add_argument('--color', '-c') # short name also accepted
12
13
14 parser.add_argument('files', help="filenames(s)") # a required positional argument
15 parser.add_argument('files', nargs="*") # 0 or more positional
```

⁹⁴<http://docs.python.org/library/sys.html>

⁹⁵<http://docs.python.org/library/optparse.html>

⁹⁶<http://docs.python.org/library/argparse.html>

```
16 parser.add_argument('files', nargs="+")    # 1 or more positional
17
18 parser.add_argument('--files', nargs="+")    # --files a.txt b.txt c.txt
19
20
21 args = parser.parse_args()
22
23 print(args.name)
24 print(args.files)
```

Basic usage of argparse

Setting up the argparse already has some (little) added value.

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.parse_args()
5
6 print('the code...')
```

Running the script without any parameter will not interfere...

```
1 $ python argparse_basic.py
2 the code...
```

If the user tries to pass some parameters on the command line, the argparse will print an error message and stop the execution.

```
1 $ python argparse_basic.py foo
2 usage: argparse_basic.py [-h]
3 argparse_basic.py: error: unrecognized arguments: foo
```

```
1 $ python argparse_basic.py -h
2 usage: argparse_basic.py [-h]
3
4 optional arguments:
5   -h, --help  show this help message and exit
```

The minimal set up of the argparse class already provides a (minimally) useful help message.

Positional argument

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('name', help='your full name')
5 args = parser.parse_args()
6
7 print(args.name)
```

```
1 $ python argparse_positional.py
2 usage: argparse_positional.py [-h] name
3 argparse_positional.py: error: too few arguments
```

```
1 $ python argparse_positional.py -h
2 usage: argparse_positional.py [-h] name
3
4 positional arguments:
5   name                your full name
6
7 optional arguments:
8   -h, --help  show this help message and exit
```

```
1 $ python argparse_positional.py Foo
2 Foo
```

```
1 $ python argparse_positional.py Foo Bar
2 usage: argparse_positional.py [-h] name
3 argparse_positional.py: error: unrecognized arguments: Bar
```

```
1 $ python argparse_positional.py "Foo Bar"
2 Foo Bar
```

Many positional argument

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('files', help='filename(s)', nargs='+')
5 args = parser.parse_args()
6
7 print(args.files)
```

```
1 $ python argparse_positional_many.py
2 usage: argparse_positional_many.py [-h] files [files ...]
3 argparse_positional_many.py: error: too few arguments
```

```
1 air:python gabor$ python argparse_positional_many.py a.txt b.txt
2 ['a.txt', 'b.txt']
```

Convert to integers

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('number', help='the number to take to the square')
5 args = parser.parse_args()
6
7 print(args.number * args.number)
```

```
1 $ python argparse_number.py abc
```

```
1 Traceback (most recent call last):
2   File "examples/argparse/argparse_number.py", line 10, in <module>
3     print(args.number * args.number)
4   TypeError: can't multiply sequence by non-int of type 'str'
```

Trying to the argument received from the command line as an integer, we get a `TypeError`. The same would happen even if a number was passed, but you could call `int()` on the parameter to convert to an integer. However there is a better solution.

The same with the following

```
1 $ python argparse_number.py 23
```

```
1 Traceback (most recent call last):
2   File "examples/argparse/argparse_number.py", line 10, in <module>
3     print(args.number * args.number)
4   TypeError: can't multiply sequence by non-int of type 'str'
```

Convert to integer

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('number', help='the number to take to the square', type=int)
5 args = parser.parse_args()
6
7 print(args.number * args.number)
```

```
1 $ argparse_type.py abc
2 usage: argparse_type.py [-h] number
3 argparse_type.py: error: argument number: invalid int value: 'abc'
```

We got a much better error message as `argparse` already found out the argument was a string and not a number as expected.

```
1 $ argparse_type.py 23
2 529
```

The `type` parameter can be used to define the type restriction and type conversion of the attributes.

Named arguments

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('--color', help='The name of the color')
5 args = parser.parse_args()
6
7 print(args.color)
```

python argparse_named.py --color Blue

```
1 Blue
```

python argparse_named.py

```
1 None
```

Named parameters are optional by default. You can pass the `required=True` parameter to make them required.

Boolean Flags

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('--color', help='The name of the color')
5 parser.add_argument('--verbose', help='Print more data',
6     action='store_true')
7 args = parser.parse_args()
8
9 print(args.color)
10 print(args.verbose)
```

python argparse_boolean.py --color Blue --verbose

```
1 Blue
2 True
```

python argparse_boolean.py

```
1 None
2 False
```

Short names

```
1 import argparse
2
3 parser = argparse.ArgumentParser()
4 parser.add_argument('--color', '-c', help='The name of the color')
5 parser.add_argument('--verbose', '-v', help='Print more data',
6     action='store_true')
7 args = parser.parse_args()
8
9 print(args.color)
10 print(args.verbose)
```

```
python argparse_shortcode.py -c Blue -v
python argparse_shortcode.py -vc Blue
```

Exercise: Command line parameters

Take the code from the color selector exercise in the files section and change it so the user can supply the name of the file where the colors are listed using the `--file filename` option.

If the user supplies an incorrect color name (which is not listed among the accepted colors) give an error message and stop execution.

Allow the user to supply a flag called `--force` that will override the color-name-validity checking and will allow any color name.

Exercise: argparse positional and named

Create a script that can accept any number of filenames, the named parameter `--machine` and the flag `--verbose`.

Like this:

```
1 python ex.py file1 file2 file3 --machine MACHINE --verbose
```

Exception handling

Hierarchy of calls

```
1 main()
2     some_process()
3     for filename in some_list:
4         handle_file(filename)
5         private_module.deal_with_file(filename)
6         private_module._helper_function(filename)
7         public_module.process_file(filename)
8         with open(filename) as fh:
9             pass
```

Handling errors as return values

- Each function that fails returns some error indicator. **None** ? An object that has an attribute “error”?
- None would be bad as that cannot indicate different errors.
- Every caller needs to check if the function returned error. If at any point we forget our system might run with hidden failures.

```
1 main()
2     .....
3     result = do_something(filename)
4     if result:
5         do_something_else(result)
```

```
1 main()
2     .....
3     result = do_something(filename)
4     do_something_else(result)
```

Handling errors as exceptions

- Only need to explicitly check for it at the level where we know what to do with the problem.
- But: Do we want our pacemaker to stop totally after missing one beat? Probably not. Or better yet: not when it is in production.

```
1 main()
2     try:
3         .....
4             result = do_something(filename)
5             do_something_else(result)
6     except Exception:
7         # decide what to do
```

A simple exception

When something goes wrong, Python throws (raises) an exception. For example, trying to divide a number by 0 won't work. If the exception is not handled, it will end the execution.

In some programming languages we use the expression “throwing an exception” in other languages the expression is “raising an exception”. I use the two expressions interchangeably.

In the next simple example, Python will print the string before the division, then it will throw an exception, printing it to the standard error that is the screen by default. Then the script stops working and the string “after” is not printed.

```
1 def div(a, b):
2     print("before")
3     print(a/b)
4     print("after")
5
6 div(1, 0)
7
8 # before
9 # Traceback (most recent call last):
10 #   File "examples/exceptions/divide_by_zero.py", line 8, in <module>
11 #     div(1, 0)
12 #   File "examples/exceptions/divide_by_zero.py", line 5, in div
13 #     print(a/b)
14 # ZeroDivisionError: integer division or modulo by zero
```

Working on a list

In a slightly more interesting example we have a list of values.
We would like to divide a number by each one of the values.
As you can see one of the values is 0 which will generate an exception.
The loop will finish early.

```
1 def div(a, b):
2     print("dividing {} by {} is {}".format(a, b, a/b))
3
4 a = 100
5 values = [2, 5, 0, 4]
6
7 for v in values:
8     div(a, v)
9
10 # dividing 100 by 2 is 50.0
11 # dividing 100 by 5 is 20.0
12 # Traceback (most recent call last):
13 # ...
14 # ZeroDivisionError: division by zero
```

We can't repair the case where the code tries to divide by 0, but it would be nice if we could get the rest of the results as well.

Catch ZeroDivisionError exception

For that, we'll wrap the critical part of the code in a "try" block. After the "try" block we need to provide a list of exception that are caught by this try-block.

You could say something like "Try this code and let all the exceptions propagate, except of the ones I listed".

As we saw in the previous example, the specific error is called ZeroDivisionError.

If the specified exception occurs within the try: block, instead of the script ending, only the try block end and the except: block is executed.

```
1 def div(a, b):
2     print("dividing {} by {} is {}".format(a, b, a/b))
3
4 a = 100
5 values = [2, 5, 0, 4]
6
7 for v in values:
8     try:
9         div(a, v)
10    except ZeroDivisionError:
```

```
11         print("Cannot divide by 0")
12
13 # dividing 100 by 2 is 50.0
14 # dividing 100 by 5 is 20.0
15 # Cannot divide by 0
16 # dividing 100 by 4 is 25.0
```

Module to open files and calculate something

Of course in the previous example, it would be probably much easier if we just checked if the number was 0, before trying to divide with it. There are many other cases when this is not possible. For example it is impossible to check if open a file will succeed, without actually trying to open the file.

In this example we open the file, read the first line which is a number and use that for division.

When the open() fails, Python throws an IOError exception.

```
1 def read_and_divide(filename):
2     print("before " + filename)
3     with open(filename, 'r') as fh:
4         number = int(fh.readline())
5         print(100 / number)
6     print("after " + filename)
```

File for exception handling example

If we have a list of files and we would like to make sure we process as many as possible without any problem caused in the middle, we can catch the exception.

We have the following list of files.

Notice that “two.txt” is missing and “zero.txt” has a 0 in it.

1 0

1 1

File two.txt is missing on purpose.

1 3

Open files - exception

```
1 import sys
2 import module
3
4 # python open_list_of_files.py one.txt zero.txt two.txt three.txt
5 files = sys.argv[1:]
6
7 for filename in files:
8     module.read_and_divide(filename)
9
10 # before one.txt
11 # 100.0
12 # after one.txt
13 # before zero.txt
14 # Traceback (most recent call last):
15 # ...
16 # ZeroDivisionError: division by zero
```

Handle divide by zero exception

Running this code will the ZeroDivisionError exception, but it will die with a IOError exception.

```
1  import sys
2  import module
3
4  # python handle_divide_by_zero.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except ZeroDivisionError:
11         print("Cannot divide by 0 in file {}".format(filename))
12
13
14 # before one.txt
15 # 100.0
16 # after one.txt
17 # before zero.txt
18 # Cannot divide by 0 in file zero.txt
19 # before two.txt
20 # IOError: [Errno 2] No such file or directory: 'two.txt'
```

Handle files - exception

We can add multiple “except” statement at the end of the “try” block and handle several exceptions. Each one in a different way.

```
1  import sys
2  import module
3
4  # python handle_both_exceptions.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except ZeroDivisionError:
11         print("Cannot divide by 0 in file {}".format(filename))
12     except IOError:
13         print("Cannot open file {}".format(filename))
14
15
16 # before one.txt
17 # 100.0
18 # after one.txt
19 # before zero.txt
20 # Cannot divide by 0 in file zero.txt
21 # before two.txt
22 # Cannot open file two.txt
23 # before three.txt
24 # 33.333333333333336
25 # after three.txt
```

Catch all the exceptions and show their type

We can also use the “except Exception” to catch all exceptions. In this case we might want to also print out the text and the type of the exception by ourselves.

```
1  import sys
2  import module
3
4  # python show_exceptions_type.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except Exception as err:
11         print("  There was a problem in " + filename)
12         print("  Text: {}".format(err))
13         print("  Name: {}".format(type(err).__name__))
14
15 # before one.txt
16 # 100.0
17 # after one.txt
18 # before zero.txt
19 #   There was a problem in zero.txt
20 #   Text: division by zero
21 #   Name: ZeroDivisionError
22 # before two.txt
23 #   There was a problem in two.txt
24 #   Text: [Errno 2] No such file or directory: 'two.txt'
25 #   Name: FileNotFoundError
26 # before three.txt
27 # 33.333333333333336
28 # after three.txt
```

List exception types

We can list more than one exceptions to be caught one after the other in a single “except” statement.

```
1  except (IOError, ZeroDivisionError):
```

```
1  import sys
2  import module
3
4  # python handle_both_exceptions.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except (ZeroDivisionError, IOError):
11         print("We have a problem with file {}".format(filename))
12
13
14  # before one.txt
15  # 100.0
16  # after one.txt
17  # before zero.txt
18  # We have a problem with file zero.txt
19  # before two.txt
20  # We have a problem with file two.txt
21  # before three.txt
22  # 33.333333333333336
23  # after three.txt
```

Exceptions

There are many kinds of exceptions in Python and each module can define its own exception types as well.

On this page you'll find the list and hierarchy of exceptions in Python.

- [exceptions](#)⁹⁷

How to raise an exception

⁹⁷<http://docs.python.org/library/exceptions.html>

As you create more and more complex applications you'll reach a point where you write a function, probably in a module that needs to report some error condition. You can raise an exception in a simple way.

```
1 def some():
2     raise Exception("Some Error")
3
4 def main():
5     try:
6         some()
7     except Exception as err:
8         print(err)
9         print("Type: " + type(err).__name__)
10
11 main()
12
13 # Some Error
14 # Type: Exception
```

Stack trace

```
1 import traceback
2
3 def bar():
4     foo()
5
6 def foo():
7     raise Exception("hi")
8
9 def main():
10    try:
11        bar()
12    except Exception as err:
13        track = traceback.format_exc()
14        print(track)
15
16    print("-----")
17    bar()
18
```

```
19
20 main()

1 Traceback (most recent call last):
2   File "stack_trace.py", line 11, in main
3     bar()
4   File "stack_trace.py", line 4, in bar
5     foo()
6   File "stack_trace.py", line 7, in foo
7     raise Exception("hi")
8 Exception: hi
9
10 -----
11 Traceback (most recent call last):
12   File "stack_trace.py", line 20, in <module>
13     main()
14   File "stack_trace.py", line 17, in main
15     bar()
16   File "stack_trace.py", line 4, in bar
17     foo()
18   File "stack_trace.py", line 7, in foo
19     raise Exception("hi")
20 Exception: hi
```

Exercies: Exception int conversion

- In the earlier example we learned how to handle both `ZeroDivisionError` and `IOError` exceptions. Now try this

```
1 cd examples/exceptions
2 python handle_both_exceptions.py one.txt zero.txt two.txt text.txt three.txt
```

```
1 before one.txt
2 100.0
3 after one.txt
4 before zero.txt
5 Cannot divide by 0 in file zero.txt
6 before two.txt
7 Cannot open file two.txt
8 before text.txt
9 Traceback (most recent call last):
10   File "handle_both_exceptions.py", line 9, in <module>
11     module.read_and_divide(filename)
12   File "/home/gabor/work/slides/python/examples/exceptions/module.py", line 4, in re\
13 ad_and_divide
14     number = int(fh.readline())
15 ValueError: invalid literal for int() with base 10: '3.14\n'
```

- This will raise a ValueError exception before handling file three.txt
- Fix it by capturing the specific exception.
- Fix by capturing “all other exceptions”.

```
1 3.14
```

Exercises: Raise Exception

- Write a function that expects a positive integer as its single parameter.
- Raise exception if the parameter is not a number.
- Raise a different exception if the parameter is not positive.
- Raise a different exception if the parameter is not whole number.

Solution: Exception int conversion (specific)

```

1  import sys
2  import module
3
4  # python handle_both_exceptions.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except ZeroDivisionError:
11         print("Cannot divide by 0 in file {}".format(filename))
12     except IOError:
13         print("Cannot open file {}".format(filename))
14     except ValueError as ex:
15         print("ValueError {} in file {}".format(ex, filename))

```

1 before one.txt
2 100.0
3 after one.txt
4 before zero.txt
5 Cannot divide by 0 in file zero.txt
6 before two.txt
7 Cannot open file two.txt
8 before text.txt
9 ValueError invalid literal for int() with base 10: '3.14\n' in file text.txt
10 before three.txt
11 33.333333333333336
12 after three.txt

Solution: Exception int conversion (all other)

```

1  import sys
2  import module
3
4  # python handle_both_exceptions.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except ZeroDivisionError:

```

```

11         print("Cannot divide by 0 in file {}".format(filename))
12     except IOError:
13         print("Cannot open file {}".format(filename))
14     except Exception as ex:
15         print("Exception type {} {} in file {}".format(type(ex).__name__, ex, filename))
16 
```

```

1  before one.txt
2  100.0
3  after one.txt
4  before zero.txt
5  Cannot divide by 0 in file zero.txt
6  before two.txt
7  Cannot open file two.txt
8  before text.txt
9  Exception type ValueError invalid literal for int() with base 10: '3.14\n' in file text.txt
10
11 before three.txt
12 33.333333333333336
13 after three.txt

```

Solution: Raise Exception

```

1 def positive(num):
2     if type(num).__name__ == 'float':
3         raise Exception("The given parameter {} is a float and not an int.".format(num))
4
5
6     if type(num).__name__ != 'int':
7         raise Exception("The given parameter {} is of type {} and not int.".format(num, type(num).__name__))
8
9
10    if num < 0:
11        raise Exception("The given number {} is not positive.".format(num))
12
13 for val in [14, 24.3, "hi", -10]:
14     print(val)
15     print(type(val).__name__)
16     try:
17         positive(val)
18     except Exception as ex:
19         print("Exception: {}".format(ex))

```

Classes - OOP - Object Oriented Programming

Why Object Oriented Programming?

- Better encapsulation of intent.
- Integration between data and functionality (attributes and methods)
- Better modelling for some part of the world.
- Another level of code-reuse.
- Clearer separation between “usage” and “implementation”. (Private data in some cases)
- Clearer connection between “classes” of things.
- In reality: avoid using “global”.

Generic Object Oriented Programming terms

- OOP differs a lot among programming languages!
- Classes (blueprints)
- Objects / instances (actual)
- Members: Attributes and Methods
- Attributes / Properties (variables - data)
- Methods (functions) (private, public, virtual)
- Inheritance (is a)
- Composition (has a)
- Constructor
- Destructor

OOP in Python

- Everything is an object
- Numbers, strings, list, ... even classes are objects.
- Class objects
- Instance objects
- Nothing is private.

OOP in Python (numbers, strings, lists)

```
1  # numbers
2  print((255).bit_length())    # 8
3  print((256).bit_length())    # 9
4
5  # strings
6  print( "hello WOrld".capitalize() )  # Hello world
7  print( ":".join(["a", "b", "c"]) )    # a:b:c
8
9
10 # lists
11 numbers = [2, 17, 4]
12 print(numbers)                # [2, 17, 4]
13
14 numbers.append(7)
15 print(numbers)                # [2, 17, 4, 7]
16
17 numbers.sort()
18 print(numbers)                # [2, 4, 7, 17]
```

OOP in Python (argparse)

```
1  import argparse
2  def get_args():
3      parser = argparse.ArgumentParser()
4      parser.add_argument('--name')
5      parser.add_argument('--email')
6
7      print(type(parser).__name__)
8      print(parser.__class__)
9
10     # print(dir(parser))
11     print( parser.format_help() )
12     parser.print_help()
13
14     return parser.parse_args()
15
16 args = get_args()
17 print(args.__class__)
18 print(args.name)
```

Create a class

```

1  # class Person(object):
2  #     pass
3
4  class Person:
5      pass
6
7  if __name__ == '__main__':
8      p = Person()
9      print(p)
10     print(type(p))
11     print(p.__class__.__name__)
12
13     members = dir(p)
14     print(members)

```

```

1  <__main__.Person object at 0x7fc4e3ec1da0>
2  <class '__main__.Person'>
3  Person
4  ['__class__', '__delattr__', '__dict__', '__dir__', '__doc__', '__eq__', '__format__\
5  ', '__ge__', '__getattr__', '__gt__', '__hash__', '__init__', '__init_subclass__\
6  _', '__le__', '__lt__', '__module__', '__ne__', '__new__', '__reduce__', '__reduce_e\
7  x__', '__repr__', '__setattr__', '__sizeof__', '__str__', '__subclasshook__', '__wea\
8  kref__']

```

In Python 2.x classes needed to inherit from 'object' in order to become 'new style' classes.

Import module containing class

```

1  import ppl
2
3  p = ppl.Person()
4  print(p)                    # <person.Person object at 0x101a8a190>
5  print(type(p))              # <class 'person.Person'>
6  print(p.__class__.__name__) # Person

```

```

1  <ppl.Person object at 0x7f973024a780>
2  <class 'ppl.Person'>
3  Person

```

Import class from module

```
1 from ppl import Person
2
3 p = Person()
4 print(p)                # <person.Person object at 0x101a8a190>
5 print(type(p))          # <class 'person.Person'>
6 print(p.__class__.__name__) # Person
```

Initialize a class - constructor, attributes

```
1 class Person():
2     def __init__(self, given_name):
3         self.name = given_name
4
5 if __name__ == '__main__':
6     p1 = Person("Joe")
7     print(p1)                # <__main__.Person object at 0x0000021EC664B358>
8     print(p1.__class__.__name__) # Person
9     print(p1.name)           # Joe
10
11    p2 = Person("Jane")
12    print(p2)                # <__main__.Person object at 0x0000021EC664B470>
13    print(p2.name)           # Jane
14
15    p1.name = "Joseph"
16    print(p1)                # <__main__.Person object at 0x0000021EC664B358>
17    print(p1.name)           # Josheph
```

Attributes are not special

```
1 class Person():
2     def __init__(self, given_name):
3         self.name = given_name
4
5 if __name__ == '__main__':
6     p1 = Person("Joe")
7     print(p1.__class__.__name__) # Person
8     print(p1.name)           # Joe
9
10    p2 = Person("Jane")
11    print(p2.name)           # Jane
12
```

```
13     p1.address = "Main street 12"
14     print(p1.address)           # Main street 12
15
16
17     print(p2.address)           # AttributeError: 'Person' object has no attribute\
18     'address'
```

Create Point class

```
1  import shapes
2
3  p = shapes.Point()
4  print(p)           # <shapes.Point instance at 0x7fb58c31ccb0>

1  class Point():
2      pass
```

Initialize a class - constructor, attributes

```
1  import shapes
2
3  p1 = shapes.Point(2, 3)
4  print(p1)           # <shapes.Point instance at 0x7fb58c31ccb0>
5  print(p1.x)         # 2
6  print(p1.y)         # 3
7
8  p1.x = 7
9  print(p1.x)         # 7

1  class Point():
2      def __init__(self, a, b):
3          self.x = a
4          self.y = b
```

Methods

```
1  import shapes
2
3  p1 = shapes.Point(2, 3)
4
5  print(p1.x)    # 2
6  print(p1.y)    # 3
7
8  p1.move(4, 5)
9  print(p1.x)    # 6
10 print(p1.y)    # 8
11
12
13 print(p1)      # <shapes.Point object at 0x7fb0691c3e48>
```

```
1  class Point():
2      def __init__(self, a, b):
3          self.x = a
4          self.y = b
5
6      def move(self, dx, dy):
7          self.x += dx
8          self.y += dy
```

Stringify class

- `repr` “should” return Python-like code
- `str` should return readable representation
- If `str` does not exist, `repr` is called instead.

```
1  import shapes
2
3  p1 = shapes.Point(2, 3)
4  print(p1)      # Point(2, 3)
```

```
1 class Point():
2     def __init__(self, x, y):
3         self.x = x
4         self.y = y
5
6     def __repr__(self):
7         return 'Point({}, {})'.format(self.x, self.y)
8
9     def move(self, dx, dy):
10         self.x += dx
11         self.y += dy
```

Inheritance

```
1 class Point():
2     def __init__(self, x, y):
3         print('__init__ of Point')
4         self.x = x
5         self.y = y
6
7     def move(self, dx, dy):
8         self.x += dx
9         self.y += dy
10
11 class Circle(Point):
12     def __init__(self, x, y, r):
13         print('__init__ of Circle')
14         super().__init__(x, y)
15         self.r = r
16
17     def area(self):
18         return self.r * self.r * 3.14
```

```
1  import shapes
2
3  c = shapes.Circle(2, 3, 10)    # __init__ of Circle
4                                # __init__ of Point
5  print(c)                      # <shapes.Circle instance at 0x7fb58c31ccb0>
6  print(c.x)                    # 2
7  print(c.y)                    # 3
8  print(c.r)                    # 10
9
10 c.move(4, 5)
11 print(c.x)                    # 6
12 print(c.y)                    # 8
13 print(c.area())               # 314.0
```

Inheritance - another level

```
1  class Point():
2      def __init__(self, x, y):
3          print('__init__ of Point')
4          self.x = x
5          self.y = y
6
7  class Circle(Point):
8      def __init__(self, x, y, r):
9          print('__init__ of Circle')
10         super().__init__(x, y)
11         self.r = r
12
13     def area(self):
14         return self.r * self.r * 3.14
15
16 class Ball(Circle):
17     def __init__(self, x, y, r, z):
18         print('__init__ of Ball')
19         super().__init__(x, y, r)
20         self.z = z
21
22
23 b = Ball(2, 3, 9, 7)
24 print(b)
25 print(b.area())
26
```

```
27 # __init__ of Ball
28 # __init__ of Circle
29 # __init__ of Point
30 # <__main__.Ball object at 0x103dea190>
31 # 254.34
```

Modes of method inheritance

- Implicit
- Override
- Extend
- Delegate - Provide

Modes of method inheritance - implicit

Inherit method

```
1 class Parent():
2     def greet(self):
3         print("Hello World")
4
5 class Child(Parent):
6     pass
7
8 p = Parent()
9 p.greet()    # Hello World
10
11 c = Child()
12 c.greet()    # Hello World
```

Modes of method inheritance - override

Replace method

```
1 class Parent():
2     def greet(self):
3         print("Hello World")
4
5 class Child(Parent):
6     def greet(self):
7         print("Hi five!")
8
9 p = Parent()
10 p.greet()
11
12 c = Child()
13 c.greet()
14
15 super(Child, c).greet()
```

```
1 Hello World
2 Hi five!
3 Hello World
```

Modes of method inheritance - extend

Extend method before or after calling original.

```
1 class Parent():
2     def greet(self):
3         print("Hello World")
4
5 class Child(Parent):
6     def greet(self):
7         print("Hi five!")
8         super().greet()
9         print("This is my world!")
10
11 p = Parent()
12 p.greet()    # Hello World
13
14 c = Child()
15 c.greet()
16
17 # Hi five!
```

```
18 # Hello World
19 # This is my world!
```

Modes of method inheritance - delegate - provide

Let the child implement the functionality.

```
1 class Parent():
2     def greet(self):
3         print("Hello", self.get_name())
4
5 class Child(Parent):
6     def __init__(self, name):
7         self.name = name
8
9     def get_name(self):
10        return self.name
11
12 # Should not create instance from Parent
13 # p = Parent()
14 # p.greet()      # AttributeError: 'Parent' object has no attribute 'get_name'
15
16 c = Child('Foo')
17 c.greet()      # Hello Foo
```

- Should we have a version of greet() in the Parent that throws an exception?
- Do we want to allow the creation of instance of the Parent class?
- Abstract Base Class (abc)

Composition - Line

When an object holds references to one or more other objects.

- [Pythagorean theorem](https://en.wikipedia.org/wiki/Pythagorean_theorem)⁹⁸

⁹⁸https://en.wikipedia.org/wiki/Pythagorean_theorem

```

1  class Point():
2      def __init__(self, x, y):
3          self.x = x
4          self.y = y
5
6  class Line():
7      def __init__(self, a, b):
8          self.a = a
9          self.b = b
10
11     def length(self):
12         return ((self.a.x - self.b.x) ** 2 + (self.a.y - self.b.y) ** 2) ** 0.5
13
14 p1 = Point(2, 3)
15 p2 = Point(5, 7)
16 blue_line = Line(p1, p2)
17
18 print(blue_line.a) # <__main__.Point object at 0x0000022174B637B8>
19 print(blue_line.b) # <__main__.Point object at 0x0000022174B3C7B8>
20 print(blue_line.length()) # 5.0

```

Some comments

- There are no private attributes. The convention is to use leading underscore to communicate to other developers what is private.
- Using the name `self` for the current object is just a consensus.

Class in function

```

1  def creator():
2      class MyClass():
3          pass
4      o = MyClass()
5      print(o.__class__.__name__) # MyClass
6
7  creator()
8  # MyClass() # NameError: name 'MyClass' is not defined

```

Serialization of instances with pickle

```
1  import pickle
2
3  class aClass(object):
4      def __init__(self, amount, name):
5          self.amount = amount
6          self.name = name
7
8
9  the_instance = aClass(42, "FooBar")
10
11  a = {
12      "name": "Some Name",
13      "address" : ['country', 'city', 'street'],
14      'repr' : the_instance,
15  }
16
17  print(a)
18
19  pickle_string = pickle.dumps(a)
20
21  b = pickle.loads(pickle_string)
22
23  print(b)
24
25  print(b['repr'].amount)
26  print(b['repr'].name)
```

Quick Class definition and usage

```
1  class Quick(object):
2      def __init__(self, name, email):
3          self.name = name
4          self.email = email
5
6  q = Quick(name = "Foo", email = "foo@bar.com")
7  print(q.name)
8  print(q.email)
```

Exercise: Add move_rad to based on radians

- From the Python: Methods take the examples/classes/methods/shapes.py and add a method

called `move_rad(dist, angle)` that accepts a distance and an angle and moved the point accordingly.

```
1 delta_x = dist * cos(angle)
2 delta_y = dist * sin(angle)
```

Exercise: Improve previous examples

- Take the previous example **Python: Inheritance - another level** and the example file called `examples/classes/inheritance/ball_shape.py` and change it so the **Ball** class will accept `x, y, z, r`.
- Add a method called `move` to the new **Ball** class that will accept `dx, dy, dz`.
- Implement a method that will return the volume of the ball.

Exercise: Polygon

- Implement a class representing a **Point**.
- Make the printing of a point instance nice.
- Implement a class representing a **Polygon**. (A list of points)
- Allow the user to “move a polygon” calling `poly.move(dx, dy)` that will change the coordinates of every point by `(dx, dy)`

```
1 class Point():
2     pass
3
4 class Polygon():
5     pass
6
7 p1 = Point(0, 0) # Point(0, 0)
8 p2 = Point(5, 7) # Point(5, 7)
9 p3 = Point(4, 9) # Point(4, 9)
10 print(p1)
11 print(p2)
12 print(p3)
13 p1.move(2, 3)
14 print(p1)      # Point(2, 3)
15
16 poly = Polygon(p1, p2, p3)
17 print(poly)    # Polygon(Point(2, 3), Point(5, 7), Point(4, 9))
18 poly.move(-1, 1)
19 print(poly)    # Polygon(Point(1, 4), Point(4, 8), Point(3, 10))
```

Exercise: Number

Turn the Number guessing game into a class. Replace every print statement with a call to an output method.

Do the same with the way you get the input.

Then create a subclass where you override these methods.

You will be able to launch the game with a hidden value you decide upon.

The input will feed a pre-defined list of values as guesses to the game and the output methods will collect the values that the game prints in a list.

Exercise: Library

Create a class hierarchy to represent a library that will be able to represent the following entities.

- Author (name, birthdate, books)
- Book (title, author, language, who_has_it_now?, is_on_waiting_list_for_whom?)
- Reader (name, birthdate, books_currently_lending)

Methods:

- write_book(title, language,)

Exercise: Bookexchange

It is like the library example, but instead of having a central library with books, each person owns and lends out books to other people.

Exercise: Represent turtle graphics

There is a cursor (or turtle) in the x-y two-dimensional sphere. It has some (x,y) coordinates. It can go forward n pixels. It can turn left n degrees. It can lift up the pencil or put it down.

Solution - Polygon

```
1  class Point:
2      def __init__(self, x, y):
3          self.x = x
4          self.y = y
5
6      def __repr__(self):
7          return "Point({}, {})".format(self.x, self.y)
8
9      def move(self, dx, dy):
10         self.x += dx
11         self.y += dy
12
13  class Polygon:
14      def __init__(self, *args):
15         self.points = args
16
17      def __repr__(self):
18         return 'Polygon(' + ', '.join(map(lambda p: str(p), self.points)) + ')'
19
20      def move(self, dx, dy):
21         for p in self.points:
22             p.move(dx, dy)
23
24  p1 = Point(0, 0) # Point(0, 0)
25  p2 = Point(5, 7) # Point(5, 7)
26  p3 = Point(4, 9) # Point(4, 9)
27  print(p1)
28  print(p2)
29  print(p3)
30  p1.move(2, 3)
31  print(p1)      # Point(2, 3)
32
33  poly = Polygon(p1, p2, p3)
34  print(poly)    # Polygon(Point(2, 3), Point(5, 7), Point(4, 9))
35  poly.move(-1, 1)
36  print(poly)    # Polygon(Point(1, 4), Point(4, 8), Point(3, 10))
```

PyPi - Python Package Index

What is PyPi?

- [pypi](http://pypi.python.org/)⁹⁹

Easy Install

- [setuptools](http://pypi.python.org/pypi/setuptools)¹⁰⁰

```
1 $ easy_install module_name
```

pip

```
1 $ pip install package_name
```

Upgrade pip

- `pip install --upgrade pip` Will probably not work on Windows because file is in use...
- `easy_install pip` Will work on Windows as well.

PYTHONPATH

```
1 export PYTHONPATH=~/.python
2 easy_install -d ~/.python Genshi
```

Virtualenv

⁹⁹<http://pypi.python.org/>

¹⁰⁰<http://pypi.python.org/pypi/setuptools>

```
1 $ pip install virtualenv
2
3 $ cd project_dir
4 $ virtualenv venv
5 $ source venv/bin/activate
6 $ ...
7 $ deactivate
```

On Windows:

```
1 venv\Source\activate.bat
```

The **virtualenv** command will create a copy of python in the given directory inside the current directory.

In the above example it will create the copy in the 'venv' directory inside the 'project_dir'.

After source-ing the 'activate' file the PATH will include the local python with a local version of **pip** and **easy_install**. This requires bash or zsh.

See also the [Python guide](http://docs.python-guide.org/en/latest/dev/virtualenvs/)^a.

^a<http://docs.python-guide.org/en/latest/dev/virtualenvs/>

Virtualenv for Python 3

```
1 virtualenv -p python3 venv3
2 source venv3/bin/activate
3 ...
4 deactivate
```

SQLite Database Access

SQLite

- `sqlite3`¹⁰¹

Connecting to SQLite database

```
1 import sqlite3
2
3 conn = sqlite3.connect("sample.db")
4 c = conn.cursor()
5
6 # use the database here
7
8 conn.close()
```

Create TABLE in SQLite

execute and commit

```
1 import sqlite3
2
3 conn = sqlite3.connect("sample.db")
4 c = conn.cursor()
5
6 try:
7     c.execute('''CREATE TABLE companies (
8         id PRIMARY KEY,
9         name VARCHAR(100) UNIQUE NOT NULL,
10        employees INTEGER DEFAULT 0)''')
11 except sqlite3.OperationalError as e:
12     print('sqlite error:', e.args[0]) # table companies already exists
13
14 conn.commit()
```

¹⁰¹<http://docs.python.org/library/sqlite3.html>

```
15
16 conn.close()
17
18 print('done')
```

INSERT data into SQLite database

Use placeholders (?) supply the data in tuples.

```
1  import sqlite3
2
3  conn = sqlite3.connect("sample.db")
4  c = conn.cursor()
5
6  my_company = 'Acme'
7
8  try:
9      c.execute('''INSERT INTO companies (name) VALUES (?)''', (my_company,))
10 except sqlite3.IntegrityError as e:
11     print('sqlite error: ', e.args[0]) # column name is not unique
12 conn.commit()
13
14 companies = [
15     ('Foo', 12),
16     ('Bar', 7),
17     ('Moo', 99),
18 ]
19
20 try:
21     sql = '''INSERT INTO companies (name, employees) VALUES (?, ?)'''
22     c.executemany(sql, companies)
23 except sqlite3.IntegrityError as e:
24     print('sqlite error: ', e.args[0]) # column name is not unique
25 conn.commit()
26
27
28 conn.close()
29
30 print('done')
```

UPDATE works quite similar, but it might have a WHERE clause.

SELECT data from SQLite database

```

1  import sqlite3
2
3  conn = sqlite3.connect("sample.db")
4  c = conn.cursor()
5
6  minimum = 0
7
8  sql = '''SELECT * FROM companies WHERE employees >= ?'''
9  for company in c.execute(sql, (minimum,)):
10     print(company)
11
12  sql = '''SELECT COUNT(*) FROM companies WHERE employees >= ?'''
13  c.execute(sql, (minimum,))
14  print(c.fetchone()[0])
15
16  conn.close()

```

Use the result as an iterator, or call the fetchone method. If the result set might be empty, then the fetchone might return None. Check for it!

A counter

```

1  """
2      Counter using an SQLite backend
3      --list          list all the counters
4      --start name    creates the counter for 'name'
5      name            counts for 'name'
6  """
7
8  import sys
9  import os
10 import sqlite3
11
12 database_file = "counter.db"
13
14 def usage():
15     print('TODO print doc')
16     conn.close()
17     exit()

```

```

18
19 def main():
20     global conn
21     conn = sqlite3.connect(database_file)
22     c = conn.cursor()
23     try:
24         c.execute('''CREATE TABLE counters (
25             id PRIMARY KEY,
26             name VARCHAR(100) UNIQUE NOT NULL,
27             count INTEGER NOT NULL
28             )''')
29     except sqlite3.OperationalError as e:
30         pass
31         # print('sqlite error:', e.args[0]) # table counters already exists
32
33     # print(len(sys.argv))
34     # print(sys.argv)
35
36     if len(sys.argv) == 1:
37         usage()
38
39     if len(sys.argv) == 2:
40         if sys.argv[1] == '--list':
41             print('List counters:')
42             for r in c.execute("SELECT name FROM counters"):
43                 print(r[0])
44             exit()
45         name = sys.argv[1]
46         c.execute("SELECT count FROM counters WHERE name = ?", (name,))
47         line = c.fetchone()
48         if line == None:
49             print("Invalid counter name '{}'.format(name))
50             exit()
51         value = line[0]
52         value = value + 1
53         c.execute("UPDATE counters SET count=? WHERE name = ?", (value, name))
54         conn.commit()
55         print("{} {}".format(name, value))
56         #print("increment counter {} was: {}".format(name, value))
57         exit()
58
59     if len(sys.argv) == 3 and sys.argv[1] == '--start':
60         name = sys.argv[2]

```

```
61     print("Start counter", name)
62     try:
63         c.execute("INSERT INTO counters (name, count) VALUES(?,?)", (name, 0))
64         conn.commit()
65     except sqlite3.IntegrityError:
66         print("Name '{}' already exists".format(name))
67         exit()
68
69     exit()
70
71     print('none')
72     usage()
73
74 main()
75
76 #print "TODO get the value of 'name' from the database"
77 # if it was not there then add
78
79
80 #try:
81 # c.execute(''INSERT INTO companies (name) VALUES ('Stonehenge')'')
82 #except sqlite3.IntegrityError as e:
83 # print 'sqlite error: ', e.args[0] # column name is not unique
84
85 #conn.commit()
86
87 #conn.close()
88
89 #print "done"
```

MySQL

Install MySQL support

- Anaconda on MS Windows: `conda install mysql-connector-python`
- Otherwise: `pip install mysql-connector`

Create database user (manually)

```
1 $ mysql -u root -p
2
3 SHOW DATABASES;
4
5 CREATE USER 'foobar'@'localhost' IDENTIFIED BY 'no secret';
6 GRANT ALL PRIVILEGES ON fb_db . * TO 'foobar'@'localhost';
7 GRANT ALL PRIVILEGES ON * . * TO 'foobar'@'%' IDENTIFIED BY 'no secret';
8 FLUSH PRIVILEGES;
9
10 exit

1 vim /etc/mysql/mysql.conf.d/mysqld.cnf
2 comment out
3 # bind-address          = 127.0.0.1
4
5 service mysql restart
```

Create database (manually)

```
1 $ mysql -u foobar -p
2
3 CREATE DATABASE fb_db;
4
5 DROP DATABASE fb_db;
6 exit
```

Create table (manually)

```
1 $ mysql -u foobar -p
2
3 USE fb_db;
4 CREATE TABLE person (
5     id INTEGER PRIMARY KEY AUTO_INCREMENT,
6     name VARCHAR(255),
7     birthdate DATE,
8     score REAL
9 );
10
11 INSERT INTO person (name, birthdate, score)
12     VALUES ("Foo Bar", "1998-05-23", 42.1)
```

Connect to MySQL

```
1 import mysql.connector
2
3 def main():
4     conn = mysql.connector.connect(
5         host = 'localhost',
6         database = 'fb_db',
7         user = 'foobar',
8         password='no secret')
9
10     print("Connected:", conn)
11
12     conn.close()
13
14 if __name__ == "__main__":
15     main()
```

```
1 $ python3 examples/mysql/connect.py
```

- Change some of the parameters and try again

Connect to MySQL and Handle exception

```
1 import mysql.connector
2
3 def main():
4     try:
5         conn = mysql.connector.connect(
6             host = 'localhost',
7             database = 'fb_db',
8             user = 'foobar',
9             password='no secret')
10    except mysql.connector.Error as e:
11        print("MySQL exception: ", e)
12        return
13    #except Exception as e:
14    #     print("Other exception", e);
15    #     return
16
17    print("Connected:", conn)
18
19    conn.close()
20
21 if __name__ == "__main__":
22     main()
```

Select data

```
1  import mysql.connector
2
3
4  def main():
5      conn = mysql.connector.connect(
6          host = 'localhost',
7          database = 'fb_db',
8          user = 'foobar',
9          password='no secret')
10
11     cursor = conn.cursor()
12     cursor.execute("SELECT * FROM person")
13
14     row = cursor.fetchone()
15     print(row)
16
17     # cursor.close() # mysql.connector.errors.InternalError: Unread result found.
18     conn.close()
19
20 if __name__ == "__main__":
21     main()
```

Select more data

```
1  import mysql.connector
2
3
4  def main():
5      conn = mysql.connector.connect(
6          host = 'localhost',
7          database = 'fb_db',
8          user = 'foobar',
9          password='no secret')
10
11     cursor = conn.cursor()
12     cursor.execute("SELECT * FROM person")
13
14     while True:
15         row = cursor.fetchone()
16         if not row:
17             break
18         print(row)
```

```
19
20     cursor.close()
21     conn.close()
22
23 if __name__ == "__main__":
24     main()
```

Select all data fetchall

```
1  import mysql.connector
2
3
4  def main():
5      conn = mysql.connector.connect(
6          host = 'localhost',
7          database = 'fb_db',
8          user = 'foobar',
9          password='no secret')
10
11     cursor = conn.cursor()
12     cursor.execute("SELECT * FROM person")
13
14     rows = cursor.fetchall()
15
16     print(len(rows))
17     for row in rows:
18         print(row)
19
20     cursor.close()
21     conn.close()
22
23 if __name__ == "__main__":
24     main()
```

Select some data fetchmany

```
1  import mysql.connector
2
3
4  def main():
5      conn = mysql.connector.connect(
6          host = 'localhost',
7          database = 'fb_db',
8          user = 'foobar',
9          password='no secret')
10
11     cursor = conn.cursor()
12     cursor.execute("SELECT * FROM person")
13
14     size = 2
15
16     while True:
17         rows = cursor.fetchmany(size)
18         if not rows:
19             break
20         print(len(rows))
21         for row in rows:
22             print(row)
23
24     cursor.close()
25     conn.close()
26

14
15     conn.close()
16
17 if __name__ == "__main__":
18     main(11)
```

Exercise MySQL

1. Create a user with a password manually.
2. Create a database manually.
3. Create a table manually for describing fleet of cars: id, license-plate, year-built, brand, owner. (Owner is the name of the owner)
4. Create a program that accepts values on the command line and inserts the data in the database
5. Create another program that lists all the cars.
6. Improve the selector program to accept command line parameter `-minage N` and `-maxage N` and show the cars within those age limits (N is a number of years e.g. 3)
7. Create program to delete a car.
8. Create program to change the owner of a car.

Exercise: MySQL Connection

Instead of hard-coding the connection details in the script, let's create an INI file that contains the connection information and use that.

```
1 [development]
2 host      = localhost
3 database  = fb_db
4 user      = foobar
5 password  = no secret
```

Solution: MySQL Connection

```
1 import configparser
2 import mysql.connector
3
4 config_file = 'examples/mysql/connect.ini'
5
6 def read_config(section = 'development'):
7     print(section)
8     cp = configparser.ConfigParser()
9     cp.read(config_file)
10    if not cp.has_section(section):
11        raise Exception("No configuration found for '{}'.format(section))
12
13    return cp[section]
14
```

```
15 def main():
16     try:
17         db = read_config()
18         print(db['password'])
19         print(db)
20         conn = mysql.connector.connect(**db)
21     except mysql.connector.Error as e:
22         print("MySQL exception: ", e)
23         return
24     except Exception as e:
25         print("Other exception", e);
26         return
27
28     if conn.is_connected():
29         print("is connected")
30     print("Connected:", conn)
31
32     conn.close()
33
34 if __name__ == "__main__":
35     main()
```

PostgreSQL

PostgreSQL install

```
1 $ sudo aptitude install postgresql
2
3 $ sudo -i -u postgres
4 $ createuser --interactive
5   Add "ubuntu" as superuser (we need a username that matches our Linux username)
6 $ createdb testdb
7
8 $ psql
9 $ sudo -u postgres psql
10
11 $ psql testdb
12 testdb=# CREATE TABLE people (id INTEGER PRIMARY KEY, name VARCHAR(100));
```

Python and Postgresql

```
1 $ sudo aptitude install python3-postgresql
2 $ sudo aptitude install python3-psycopg2
```

PostgreSQL connect

```
1 import psycopg2
2
3 try:

12     for r in cur.fetchall():
13         print(r)
14 except Exception as e:
15     print(e)
```

DELETE

```
1  import psycopg2
2
3  try:
4      conn = psycopg2.connect("postgresql:///testdb")
5  except Exception as e:
6      print("I am unable to connect to the database: ", e)
7
8  cur = conn.cursor()
9
10 try:
11     cur.execute("DELETE FROM people")
12     conn.commit()
13 except Exception as e:
14     print(e)
15
16 try:
17     cur.execute("SELECT * from people")
```

```
18     for r in cur.fetchall():
19         print(r)
20 except Exception as e:
21     print(e)
```

SQLAlchemy

SQLAlchemy hierarchy

- ORM
- Table, Metadata, Reflection, DDL - standardized language
- Engine - standardize low-level access (placeholders)

SQLAlchemy engine

```
1 engine = create_engine('sqlite:///test.db')           # relative path
2 engine = create_engine('sqlite:///full/path/to/test.db') # full path
3 engine = create_engine('sqlite://')                   # in memory database
```

PostgreSQL

```
1 engine = create_engine('postgresql://user:password@hostname/dbname')
2 engine = create_engine('postgresql+psycopg2://user:password@hostname/dbname')
```

MySQL

```
1 engine = create_engine("mysql://user:password@hostname/dbname", encoding='latin1') #\
2 defaults to utf-8
```

SQLAlchemy autocommit

Unlike the underlying database engines, SQLAlchemy uses autocommit.

That is, usually we don't need to call `commit()`, but if we would like to have a transaction we need to

start it using `begin()` and end it either with `commit()` or with `rollback()`.

SQLAlchemy engine CREATE TABLE

```
1  import os
2  from sqlalchemy import create_engine
3
4  dbname = 'test.db'
5  if os.path.exists(dbname):
6      os.unlink(dbname)
7
8  engine = create_engine('sqlite:/// ' + dbname)  # Engine
9
10 engine.execute('''
11     CREATE TABLE person (
12         id INTEGER PRIMARY KEY,
13         name VARCHAR(100) UNIQUE,
14         balance INTEGER NOT NULL
15     );
16 ''')
```

SQLAlchemy engine INSERT

```
1  import os
2  from sqlalchemy import create_engine
3
4  dbname = 'test.db'
5
6  engine = create_engine('sqlite:/// ' + dbname)
7
8  engine.execute('INSERT INTO person (name, balance) VALUES (:name, :balance)', name =\
9      'Joe', balance = 100)
10 engine.execute('INSERT INTO person (name, balance) VALUES (:name, :balance)', name =\
11     'Jane', balance = 100)
12 engine.execute('INSERT INTO person (name, balance) VALUES (:name, :balance)', name =\
13     'Melinda', balance = 100)
14 engine.execute('INSERT INTO person (name, balance) VALUES (:name, :balance)', name =\
15     'George', balance = 100)
```

SQLAlchemy engine SELECT

```

1  from sqlalchemy import create_engine
2
3  dbname = 'test.db'
4
5  engine = create_engine('sqlite:/// ' + dbname)
6  result = engine.execute('SELECT * FROM person WHERE id=:id', id=3)
7
8  print(result)          # <sqlalchemy.engine.result.ResultProxy object at 0x1013c9d\
9  a0>
10
11 row = result.fetchone()
12 print(row)             # (3, 'Melinda', 100) - Its a tuple
13 print(row['name'])      # Melinda           - And a dictionary
14 print(row.name)        # Melinda          - and object with methods for the columns
15
16 for k in row.keys():    # keys also works on it
17     print(k)           # id, name, balance
18
19 result.close()

```

SQLAlchemy engine SELECT all

```

1  import os
2  from sqlalchemy import create_engine
3
4  dbname = 'test.db'
5
6  engine = create_engine('sqlite:/// ' + dbname)
7  result = engine.execute('SELECT * FROM person')
8
9  for row in result:
10     print(row)
11
12 result.close()
13
14 # (1, 'Joe', 100)
15 # (2, 'Jane', 100)
16 # (3, 'Melinda', 100)
17 # (4, 'George', 100)

```

SQLAlchemy engine SELECT fetchall

```
1 from sqlalchemy import create_engine
2
3 dbname = 'test.db'
4
5 engine = create_engine('sqlite:/// ' + dbname)
6 result = engine.execute('SELECT * FROM person WHERE id >= :id', id=3)
7
8 rows = result.fetchall()
9 print(rows)          # [(3, 'Melinda', 100), (4, 'George', 100)]
10
11 result.close()
```

SQLAlchemy engine SELECT aggregate

```
1 from sqlalchemy import create_engine
2
3 dbname = 'test.db'
4
5 engine = create_engine('sqlite:/// ' + dbname)
6 result = engine.execute('SELECT COUNT(*) FROM person')
7
8 r = result.fetchone()[0]
9 print(r)
10
11 result.close()
```

SQLAlchemy engine SELECT IN

```
1 from sqlalchemy import create_engine
2
3 dbname = 'test.db'
4
5 engine = create_engine('sqlite:/// ' + dbname)
6
7 results = engine.execute("SELECT * FROM person WHERE name IN ('Joe', 'Jane')")
8 print(results.fetchall()) # [(2, 'Jane', 100), (1, 'Joe', 100)]
9
10 # engine.execute("SELECT * FROM person WHERE name IN (:a0, :a1)", a0 = 'Joe', a1 = '\
11 Jane')
```

SQLAlchemy engine SELECT IN with placeholders

```
1  from sqlalchemy import create_engine
2
3  dbname = 'test.db'
4
5  engine = create_engine('sqlite:/// ' + dbname)
6
7
8  names = ['Joe', 'Jane']
9  placeholders = []
10 data = {}
11 for i in range(len(names)):
12     placeholders.append(':a' + str(i))
13     data['a' + str(i)] = names[i]
14
15 # print(placeholders) # [':a0', ':a1']
16 # print(data)         # {'a0': 'Joe', 'a1': 'Jane'}
17
18 sql = "SELECT * FROM person WHERE name IN ({})".format(', '.join(placeholders))
19 # print(sql) # SELECT * FROM person WHERE name IN (:a0, :a1)
20
21 #results = engine.execute(sql, a0 = 'Jane', a1 = 'Joe')
22 results = engine.execute(sql, **data)
23 print(results.fetchall()) # [(2, 'Jane', 100), (1, 'Joe', 100)]
```

SQLAlchemy engine connection

```
1  from sqlalchemy import create_engine
2
3  dbname = 'test.db'
4
5  engine = create_engine('sqlite:/// ' + dbname)
6
7  conn = engine.connect()
8  results = conn.execute('SELECT balance, name FROM person WHERE id < :id', id = 3)
9  print(results.fetchall()) # [(100, 'Joe'), (100, 'Jane')]
10 conn.close()
```

SQLAlchemy engine transaction

```
1  from sqlalchemy import create_engine
2
3  dbname = 'test.db'
4
5  engine = create_engine('sqlite:/// ' + dbname)
6
7  conn = engine.connect()
8
9  trans = conn.begin()
10
11  src = 'Joe'
12  dst = 'Jane'
13  payment = 3
14
15  results = conn.execute("SELECT balance, name FROM person WHERE name = :name", name =\
16  src)
17  src_balance = results.fetchone()[0]
18  results.fetchall()
19  print(src_balance)
20
21
22  results = conn.execute("SELECT balance, name FROM person WHERE name = :name", name =\
23  dst)
24  dst_balance = results.fetchone()[0]
25  results.fetchall()
26  print(dst_balance)
27
28  conn.execute('UPDATE person SET balance = :balance WHERE name=:name', balance = src_\
29  balance - payment, name = src)
30  conn.execute('UPDATE person SET balance = :balance WHERE name=:name', balance = dst_\
31  balance + payment, name = dst)
32
33  trans.commit()
34
35  # trans.rollback()
36
37  conn.close()
38
39  results = engine.execute("SELECT * FROM person")
40  print(results.fetchall())
```

SQLAlchemy engine using context managers

```
1 with engine.begin() as trans:
2     conn.execute(...)
3     conn.execute(...)
4     raise Exception() # for rollback
```

Exercise: Create table

Create the following schema

```
1 CREATE TABLE node (
2     id      INTEGER PRIMARY KEY,
3     name    VARCHAR(100)
4 );
5
6 CREATE TABLE interface (
7     id      INTEGER PRIMARY KEY,
8     node_id INTEGER NOT NULL,
9     ipv4    VARCHAR(15) UNIQUE,
10    ipv6    VARCHAR(80) UNIQUE,
11    FOREIGN KEY (node_id) REFERENCES node(id)
12 );
13
14 CREATE TABLE connection (
15     a      INTEGER NOT NULL,
16     b      INTEGER NOT NULL,
17     FOREIGN KEY (a) REFERENCES interface(id),
18     FOREIGN KEY (b) REFERENCES interface(id)
19 );
```

Insert a few data items. Write a few select statements.

SQLAlchemy Metada

Describe the Schema, the structure of the database (tables, columns, constraints, etc.) in Python.

- SQL generation from the metadata, generate to a schema.
- Reflection (Introspection) - Create the metadata from an existing database, from an existing schema.

```
1  from sqlalchemy import MetaData
2  from sqlalchemy import Table, Column
3  from sqlalchemy import Integer, String
4
5  metadata = MetaData()
6  user_table = Table('user', metadata,
7                     Column('id', Integer, primary_key=True),
8                     Column('name', String(100), unique=True),
9                     Column('balance', Integer, nullable=False)
10                    )
11  print(user_table.name)
12  print(user_table.c.name)
13  print(user_table.c.id)
14
15  print(user_table.c)
16  print(user_table.columns) # A bit like a Python dictionary, but it is an associativ\
17  e array
18
19
20
21  from sqlalchemy import create_engine
22  engine = create_engine('sqlite://')
23  metadata.create_all(engine)
24
25  from sqlalchemy import ForeignKey
26
27  address_table = Table('address', metadata,
28                       Column('id', Integer, primary_key=True),
29                       Column('street', String(100)),
30                       Column('user_id', Integer, ForeignKey('user.id'))
31                      )
32  address_table.create(engine)
33
34  from sqlalchemy import Unicode, UnicodeText, ForeignKeyConstraint, DateTime
35
36  story_table = Table('story', metadata,
37                     Column('id', Integer, primary_key=True),
38                     Column('version', Integer, primary_key=True),
39                     Column('headline', Unicode(100), nullable=False),
40                     Column('body', UnicodeText)
41                    )
42  published_table = Table('published', metadata,
43                          Column('id', Integer, primary_key=True),
```

```

44         Column('timestamp', DateTime, nullable=False),
45         Column('story_id', Integer, nullable=False),
46         Column('version', Integer, nullable=False),
47         ForeignKeyConstraint(
48             ['story_id', 'version_id'],
49             ['story.story_id', 'story.version_id']
50         )
51     )
52
53
54     conn.execute(user_table.insert(), [
55         {'username': 'Jack', 'fullname': 'Jack Burger'},
56         {'username': 'Jane', 'fullname': 'Jane Doe'}
57     ])
58
59     from sqlalchemy import select
60     select_stmt = select([user_table.c.username, user_table.c.fullname]).where(user_table\
61 e.c.username == 'ed')
62     result = conn.execute(select_stmt)
63     for row in result:
64         print(row)
65
66     select_stmt = select([user_table])
67     conn.execute(select_stmt).fetchall()
68
69     select_stmt = select([user_table]).where(
70         or_(
71             user_table.c.username == 'ed',
72             user_table.c.username == 'wendy'
73         )
74     )
75
76     joined_obj = user_table.join(address_table, user_table.c.id = address_table.c.user_id)
77     d)

```

SQLAlchemy types

- Integer() - INT
- String() - ASCII strings - VARCHAR
- Unicode() - Unicode string - VARCHAR or NVARCHAR depending on database
- Boolean() - BOOLEAN, INT, TINYINT depending on db support for boolean type
- DateTime() - DATETIME or TIMESTAMP returns Python datetime() objects.

- Float() - floating point values
- Numeric() - precision numbers using Python Decimal()

SQLAlchemy ORM - Object Relational Mapping

- Domain model
- Mapping between Domain Object - Table Row

SQLAlchemy ORM create

```
1  import os
2  from sqlalchemy import Column, ForeignKey, Integer, String
3  from sqlalchemy.ext.declarative import declarative_base
4  from sqlalchemy.orm import relationship
5  from sqlalchemy import create_engine
6
7  Base = declarative_base()
8
9
10 class Person(Base):
11     __tablename__ = 'person'
12     id = Column(Integer, primary_key=True)
13     name = Column(String(250), nullable=False, unique=True)
14
15 class Genre(Base):
16     __tablename__ = 'genre'
17     id = Column(Integer, primary_key=True)
18     name = Column(String(250), nullable=False, unique=True)
19

9
10 session = Session(engine)
11
12 movies = session.query(Movie).all()
13 for m in movies:
14     print(m.title, "-", m.genre.name)
```

SQLAlchemy ORM SELECT and INSERT

```
1  from sqlalchemy import create_engine
2  from sqlalchemy.orm import Session
3  from orm_create_db import Base, Genre, Movie, Person, Cast
4
5  dbname = 'imdb.db'
6  engine = create_engine('sqlite:/// ' + dbname)
7
8  Base.metadata.bind = engine
9
10 session = Session(engine)
11
12 animation = session.query(Genre).filter(Genre.name == 'Animation').one()
13 session.add(Movie(title = "Moana", genre = animation))
14 session.add(Movie(title = "Trolls", genre = animation))
15
16 action = session.query(Genre).filter(Genre.name == 'Action').one()
17 session.add(Movie(title = "Power Rangers", genre = action))
18
19 comedy = session.query(Genre).filter(Genre.name == 'Comedy').one()
20 session.add(Movie(title = "Ghostbuster", genre = comedy))
21
22
23 session.commit()
```

SQLAlchemy ORM UPDATE

```
1  from sqlalchemy import create_engine
2  from sqlalchemy.orm import Session
3  from orm_create_db import Base, Genre, Movie, Person, Cast
4
5  dbname = 'imdb.db'
6  engine = create_engine('sqlite:/// ' + dbname)
7
8  Base.metadata.bind = engine
9
10 session = Session(engine)
11
12 movie = session.query(Movie).filter(Movie.title == 'Ghostbuster').one()
13 print(movie.title)
14 movie.title = 'Ghostbusters'
15 session.commit()
16
```

```
17 print(movie.title)
```

SQLAlchemy ORM logging

```
1 from sqlalchemy import create_engine
2 from sqlalchemy.orm import Session
3 from orm_create_db import Base, Genre, Movie, Person, Cast
4
5 import logging
6
7 logging.basicConfig()
8 logging.getLogger('sqlalchemy.engine').setLevel(logging.INFO)
9
10 logger = logging.getLogger('demo')
11 logger.setLevel(logging.INFO)
12
13 dbname = 'imdb.db'
14 engine = create_engine('sqlite:/// ' + dbname)
15
16 Base.metadata.bind = engine
17
18 session = Session(engine)
19
20
21 logger.info("Selecting all")
22 movies = session.query(Movie).all()
23 for m in movies:
24     logger.info("-----")
25     #print(m.title, "-", m.genre_id)
26     print(m.title, "-", m.genre.name)
```

Solution: Create table

Create the followig schema

```
1  from sqlalchemy import create_engine
2  from sqlalchemy import MetaData
3  from sqlalchemy import Table, Column
4  from sqlalchemy import Integer, String
5  from sqlalchemy import ForeignKey
6
7  metadata = MetaData()
8
9  node_table = Table('node', metadata,
10                     Column('id', Integer, primary_key=True),
11                     Column('name', String(100), unique=True)
12                     )
13
14  interface_table = Table('interface', metadata,
15                           Column('id', Integer, primary_key=True),
16                           Column('node_id', Integer, ForeignKey('node.id'), nullable=False),
17                           Column('ipv4', String(14), unique=True),
18                           Column('ipv6', String(80), unique=True),
19                           )
20
21  connection_table = Table('connection', metadata,
22                            Column('a', Integer, ForeignKey('interface.id'), nullable=False),
23                            Column('b', Integer, ForeignKey('interface.id'), nullable=False)
24                            )
25
26  engine = create_engine('sqlite://', echo=True)
27  metadata.create_all(engine)
```

Exercise: Inspector

Use the inspector to list all the tables and all the columns in every table.

```
1  from sqlalchemy import create_engine
2  from sqlalchemy import MetaData
3  from sqlalchemy import Table, Column
4  from sqlalchemy import Integer, String
5  from sqlalchemy import ForeignKey
6
7  metadata = MetaData()
8
9  node_table = Table('node', metadata,
10                     Column('id', Integer, primary_key=True),
```

```

11         Column('name', String(100), unique=True)
12     )
13
14 interface_table = Table('interface', metadata,
15     Column('id', Integer, primary_key=True),
16     Column('node_id', Integer, ForeignKey('node.id'), nullable=False),
17     Column('ipv4', String(14), unique=True),
18     Column('ipv6', String(80), unique=True),
19     )
20
21 connection_table = Table('connection', metadata,
22     Column('a', Integer, ForeignKey('interface.id'), nullable=False),
23     Column('b', Integer, ForeignKey('interface.id'), nullable=False)
24     )
25
26 engine = create_engine('sqlite://', echo=True)
27 metadata.create_all(engine)
28
29
30 m2 = MetaData()
31 m2_node_table = Table('node', m2, autoload=True, autoload_with=engine)
32 m2_interface_table = Table('interface', m2, autoload=True, autoload_with=engine)
33 print(m2_node_table.columns)
34 print(m2_interface_table.columns)
35 print(m2_node_table.__repr__())
36
37 from sqlalchemy import inspect
38
39 inspector = inspect(engine)
40 inspector.get_columns('address')
41 inspector.get_foreign_keys('address')

```

SQLAlchemy CREATE and DROP

- `metadata.create_all(engine, checkfirst=True|False)` emits CREATE statement for all tables.
- `table.create(engine, checkfirst=False|True)` emits CREATE statement for a single table.
- `metadata.drop_all(engine, checkfirst=True|False)` emits DROPT statement for all the tables.
- `table.drop(engine, checkfirst=False|True)` emits DROPT statement for a single table.

metada can create (or drop) the tables in the correct order to maintain the dependencies.

SQLAlchemy Notes

- Multi-column primary key (composite primary key).
- Composite foreign key.

SQLAlchemy Meta SQLite CREATE

```
1  from sqlalchemy import create_engine
2  import os
3  from sqlite_meta_schema import get_meta
4
5  dbname = 'test.db'
6  if os.path.exists(dbname):
7      os.unlink(dbname)
8  engine = create_engine('sqlite:///test.db')
9
10 metadata = get_meta()
11 metadata.create_all(engine)

1  from sqlalchemy import MetaData
2  from sqlalchemy import Table, Column
3  from sqlalchemy import Integer, String
4  from sqlalchemy import ForeignKey
5
6
7  def get_meta():
8      metadata = MetaData()
9
10     node_table = Table('node', metadata,
11                        Column('id', Integer, primary_key=True),

12 # print(inspector)
13 # print(inspector.get_columns('address'))
14 # print(inspector.get_foreign_keys('address'))
15
16 insp = reflection.Inspector.from_engine(engine)
17 print(insp.get_table_names())

```

SQLAlchemy Meta INSERT

```

1

```

SQLAlchemy Meta SELECT

```

1

```

NoSQL

Types of NoSQL databases

- Document oriented - MongoDB
- Key-Value store - Redis
- Graph - Neo4j
- Tuple store - Apache River, TIBCO

MongoDB

MongoDB CRUD

- Create, Read, Update, Delete

Install MongoDB support

- Otherwise: `pip install pymongo`

Python MongoDB insert

```
1  from pymongo import MongoClient
2  import datetime
3
4  client = MongoClient()
5  db = client.demo
6
7  foo = {
8      'name'      : 'Foo',
9      'email'     : 'foo@example.com',
10     'birthdate' : datetime.datetime.strptime('2002-01-02', '%Y-%m-%d'),
11     'student'   : True,
12 }
13
14 bar = {
15     'name'      : 'Bar',
16     'email'     : 'bar@example.com',
17     'birthdate' : datetime.datetime.strptime('1998-08-03', '%Y-%m-%d'),
18     'student'   : True,
19     'teacher'   : False,
20 }
21
22 zorg = {
23     'name'      : 'Zorg',
24     'email'     : 'zorg@corp.com',
```

```

25     'birthdate' : datetime.datetime.strptime('1995-12-12', '%Y-%m-%d'),
26     'teacher'    : True,
27 }
28
29
30 db.people.insert(foo)
31 db.people.insert(bar)
32 db.people.insert(zorg)

```

MongoDB CLI

```

1  $ mongo
2  > help
3  ...
4  > show dbs

7  db.people.remove({ 'name' : 'Zorg'})
8  for p in db.people.find():
9      print(p)
```

Redis

Redis CLI

`redis-cli`¹⁰³

```
1 $ redis-cli
2 > set name foo
3 > get name
4 > set name "foo bar"
5 > get name
6
7 > set a 1
8 > get a
9 > incr a
10 > get a
11
12 > set b 1
13 > keys *
14 > del b
```

Redis list keys

```
1 import redis
2 r = redis.StrictRedis()
3
4 for k in r.keys('*'):
5     print(k)
```

Redis set get

¹⁰³<https://redis.io/topics/rediscli>

```
1 import redis
2 r = redis.StrictRedis()
3
4 r.set("name", "some value")
5 print(r.get("name"))
```

Redis incr

```
1 import redis
2 r = redis.StrictRedis()
3
4 r.set("counter", 40)
5 print(r.get("counter"))
6 print(r.incr("counter"))
7 print(r.incr("counter"))
8 print(r.get("counter"))
```

Redis incrby

```
1 import redis
2 r = redis.StrictRedis()
3
4 r.set("counter", 19)
5 print(r.get("counter"))
6 print(r.incrby("counter", 23))
7 print(r.get("counter"))
```

Redis setex

Set with expiration time in seconds.

```
1  import redis
2  import time
3  r = redis.StrictRedis()
4
5
6  r.setex("login", 2, 'foobar')
7  print(r.get("login"))    # 'foobar'
8  time.sleep(1)
9  print(r.get("login"))    # 'foobar'
10 time.sleep(1)
11 print(r.get("login"))    # None
```

Web client

urllib the web client

```
1  import urllib
2
3  # f is like a filehand for http requests, but it cannot be user "with"
4  # Only works in Python 2
5  f = urllib.urlopen('http://python.org/')
6  html = f.read()    # is like a get() request
7  f.close()
8
9  print(html)
10
11
12  # retrieve a file and save it locally:
13  urllib.urlretrieve('http://www.python.org/images/python-logo.gif', 'logo.gif')
```

urllib2 the web client

urllib2 is better than urllib as it will indicate if there was an error retrieving

```
1  import urllib2
2
3  # f is like a filehand for http requests
4  f = urllib2.urlopen('http://python.org/')
5  html = f.read()    # is like a get() request
6  f.close()
7  print(html)
8
9
10 try:
11     f = urllib2.urlopen('http://python.org/some_missing_page')
12     html = f.read()
```

```
13     f.close()
14     print(html)
15 except urllib2.HTTPError as e:
16     print(e)    # HTTP Error 404: OK
```

httpbin.org

- httpbin.org¹⁰⁴
- [source](#)¹⁰⁵

requests get

```
1 import requests
2
3 r = requests.get('http://httpbin.org/')
4 print(type(r))
5 print(r.status_code)
6 print(r.headers)
7 print(r.headers['content-type'])
```

Exercise: Flask calculator

Write a web application that has two entry boxes and a button and that will add the two numbers inserted into the entry boxes.

Static files

```
1 from flask import Flask, request, render_template, url_for
2 app = Flask(__name__)
3
4 @app.route("/")
5 def main():
6     return render_template('main.html')
7
8 @app.route("/other")
9 def other():
10    return render_template('other.html',
11                           img_path = url_for('static', filename='img/python.png'))
```

```
1 <h1>Main page</h1>
2 
3 <p>
4 <a href="/other">other</a>
```

```
1 <h2>Other page</h2>
2 img_path: {{ img_path }}
3 <p>
4 
5 <p>
6 <a href="/">main</a>
```

```
1 .
2 |─ app.py
3 |─ static
4 |   └─ img
5 |       └─ python.png
6 └─ templates
    |─ main.html
    └─ other.html
```

Flask Logging

```
1 from flask import Flask
2 app = Flask(__name__)
3
4 @app.route("/")
5 def main():
6     app.logger.debug("Some debug message")
7     app.logger.warning("Some warning message")
8     app.logger.error("Some error message")
9     return "Hello World"
```

Flask: Counter

```
1  from flask import Flask
2  app = Flask(__name__)
3
4  counter = 1
5
6  @app.route("/")
7  def main():
8      global counter
9      counter += 1
10     return str(counter)
```

Access the page from several browsers. There is one single counter that lives as long as the process lives.

Color selector without session

```
1  from flask import Flask, request, render_template
2  import re
3  app = Flask(__name__)
4
5  @app.route("/", methods=['GET', 'POST'])
6  def main():
7      color = "FFFFFF"
8      new_color = request.form.get('color', '')
9      if re.search(r'^[0-9A-F]{6}$', new_color):
10         color = new_color
11
12     return render_template('main.html', color = color)
```

```
1  <style>
2  * {
3      background-color: #{{ color }};
4  }
5  </style>
6
7  <form method="POST">
8  <input name="color" value="{{ color }}">
9  <input type="submit" value="Set">
10 </form>
11 <p>
12 <a href="/">home</a>
```

Session management

```
1  from flask import Flask, request, render_template, session
2  import re
3  app = Flask(__name__)
4  app.secret_key = 'blabla'
5
6  @app.route("/", methods=['GET', 'POST'])
7  def main():
8      color = session.get('color', 'FFFFFF')
9      app.logger.debug("Color: " + color)
10
11     new_color = request.form.get('color', '')
12     if re.search(r'^[0-9A-F]{6}$', new_color):
13         app.logger.debug('New color: ' + new_color)
14         session['color'] = new_color
15         color = new_color
16
17     return render_template('main.html', color = color)
```

Flask custom 404 page

```
1  from flask import Flask

2 app = Flask(__name__)
3
4 @app.route("/")
5 def main():
6     return '''
7     Main
8     <a href="/bad">bad</a>
9     '''
10
11 @app.route("/bad")
12 def bad():
13     raise Exception("This is a bad page")
14     return 'Bad page'
15
16 @app.errorhandler(500)
17 def not_found(err):
18     #raise Exception("Oops")
19     return "Our Page crashed", 500
```

Flask URL routing

The mapping of the path part of a URL, so the one that comes after the domain name and after the port number (if it is included) is the path. Mapping that to a function call is called routing.

In the following pages we are going to see several examples on how to map routes to functions.

It is also called “url route registration”.

Flask Path params

```

1  from flask import Flask, jsonify
2  app = Flask(__name__)
3
4  @app.route("/")
5  def main():
6      return '''
7      Main<br>
8      <a href="/user/23">23</a><br>
9      <a href="/user/42">42</a><br>
10     <a href="/user/Joe">Joe</a><br>
11     '''
12
13  @app.route("/user/<uid>")
14  def api_info(uid):
15      return uid

```

1 FLASK_APP=app.py FLASK_DEBUG=0 flask run

Flask Path params (int)

```

1  from flask import Flask, jsonify
2  app = Flask(__name__)
3
4  @app.route("/")
5  def main():
6      return '''
7      Main<br>
8      <a href="/user/23">23</a><br>
9      <a href="/user/42">42</a><br>
10     <a href="/user/Joe">Joe</a><br>
11     '''
12
13  @app.route("/user/<int:uid>")
14  def api_info(uid):
15      return str(uid)

```

1 FLASK_APP=app.py FLASK_DEBUG=0 flask run

Flask Path params add (int)

```

1  from flask import Flask, jsonify
2  app = Flask(__name__)
3
4  @app.route("/")
5  def main():
6      return '''
7      Main <a href="/add/23/19">add</a>
8      '''
9
10 @app.route("/add/<int:a>/<int:b>")
11 def api_info(a, b):
12     return str(a+b)

```

```
1 FLASK_APP=app.py FLASK_DEBUG=0 flask run
```

Flask Path params add (path)

- Accept any path, including slashes:

```

1  from flask import Flask, jsonify
2  app = Flask(__name__)
3
4  @app.route("/")
5  def main():
6      return '''
7      Main<br>
8      <a href="/user/name">/user/name</a><br>
9      <a href="/user/other/dir">/user/other/dir</a><br>
10     <a href="/user/hi.html">/usre/hi.html</a><br>
11     '''
12
13 @app.route("/user/<path:fullpath>")
14 def api_info(fullpath):
15     return fullpath

```

```
1 FLASK_APP=app.py FLASK_DEBUG=0 flask run
```

Jinja loop, conditional, include

```

1  .

```

Interactive shell

The Python interactive shell

Type python without any arguments on the command line and you'll get into the Interactive shell of Python.

In the interactive shell you can type:

```
1 >>> print "hello"
2 hello
3
4 >>> "hello"
5 'hello'
6
7 >>> 6
8 6
9
10 >>> len("abc")
11 3
12
13 >>> "abc" + 6
14 Traceback (most recent call last):
15   File "<stdin>", line 1, in <module>
16 TypeError: cannot concatenate 'str' and 'int' objects
17
18 >>> "abc" + str(6)
19 'abc6'
```

REPL - Read Evaluate Print Loop

A variable comes to existence the first time we assign a value to it. It points to an object and that object knows about its type.

```
1 >>> a = "abc"
2 >>> len(a)
3 3
4
5 >>> a = '3'
6 >>> a + 3
7 Traceback (most recent call last):
8   File "<stdin>", line 1, in <module>
9   TypeError: cannot concatenate 'str' and 'int' objects
10
11 >>> int(a) + 3
12 6
13
14 >>> a = '2.3'
15 >>> float(a) + 1
16 3.3
```

Using Modules

Python has lots of standard (and not standard) modules. You can load one of them using the `import` keyword. Once loaded, you can use functions from the module or access its objects. For example the `sys` module has a `sys.version` and a `sys.executable` variable.

```
1 >>> import sys
2 >>> sys.version
3 '2.7.3 (default, Apr 10 2012, 23:24:47) [MSC v.1500 64 bit (AMD64)]'

1 >>> sys.executable
2 'c:\\Python27\\python.exe'
```

You can also load specific object directly into your code.

```
1 >>> from sys import executable
2 >>> executable
3 'c:\\Python27\\python.exe'
```

To quit the interpreter call the `exit()` function.

```
1 >>> exit
2 Use exit() or Ctrl-Z plus Return to exit
```

The import binds the word sys to whatever it loaded from the file.

Getting help

```
1 >>> help
2 Type help() for interactive help, or help(object) for help about object.
3 >>> help() - entering an internal shell:
4 ...
5 help> dir - explains about the dir command. Navigate using SPACE/ENTER/q
6 help> Ctrl-D - to quite, (Ctrl-Z ENTER on Windows)
7 >>> help(dir) - the same explanation as before
8
9 >>> dir()
10 ['__builtins__', '__doc__', '__name__', '__package__']
11 >>> dir("") - list of string related methods
12 ['__add__', '__class__', ... 'upper', 'zfill']
13
14 >>> dir(1) - list of integer related methods
15 ['__abs__', '__add__', ... 'numerator', 'real']
16
17 >>> dir(__builtins__)
18 ... - functions available in python
19
20 >>> help(abs) - explain how abs() works
21 >>> help(sum)
22 >>> help(zip)
23 >>> help(int)
24 >>> help(str)
25
26 >>> help("").upper) - explain how the upper method of strings work
27
28 >>> import sys
29 >>> dir(sys)
30 >>> help(sys)
31 >>> help(sys)
32 >>> help(sys.path)
33 >>> help(sys.path.pop)
```

Exercise: Interactive shell

- Start the REPL and check the examples.
- Check the documentation in the REPL.

Testing Demo

How do you test your code?

* What kind of things do you test?

- Web application?
- Command line application?
- Databases?
- ...

What is testing?

- Fixture + Input = Expected Output

What is testing really?

- Fixture + Input = Expected Output + Bugs

Testing demo - AUT - Application Under Test

Given the following module with a single function, how can we use this function and how can we test it?

```
1 def add(x, y):  
2     return x * y  
3  
4 # Yes, I know there is a bug in this code!
```

Testing demo - use the module

```
1  import mymath
2  import sys
3
4  if len(sys.argv) != 3:
5      exit(f"Usage {sys.argv[0]} NUMBER NUMBER")
6
7  a = int(sys.argv[1])
8  b = int(sys.argv[2])
9
10 print(mymath.add(a, b) )
```

```
1  python use_mymath.py 2 2
2  4
```

Testing demo: doctets

```
1  def add(x, y):
2      """
3      >>> add(2, 2)
4      4
5      """
6      return x * y
```

```
1  python -m doctest mymath_doctest_first.py
2  echo $?
3  0
4
5  echo %ERRORLEVEL%
6  0
```

```
1  def add(x, y):
2      """
3      >>> add(2, 2)
4      4
5      >>> add(3, 3)
6      6
7      """
8      return x * y
```

```

1 python -m doctest mymath_doctest.py
2 echo $?
3 1

Testing demo: pytest run unittest

```
1 pytest -v test_with_unittest.py
```

Exercise: Testing demo

- An [anagram](https://en.wikipedia.org/wiki/Anagram)¹²¹ is a pair of words that are created from exactly the same set of characters, but of different order.
- For example **listen** and **silent**
- Or **bad credit** and **debit card**
- Given the following module with the `is_anagram` function write tests for it. (in a file called `test_anagram.py`)
- Write a failing test as well.
- Try `doctest`, `unittest`, and `pytest` as well.

```
1 def is_anagram(a_word, b_word):  
2     return sorted(a_word) == sorted(b_word)
```

Sample code to use the Anagram module.

```
1 from anagram import is_anagram  
2 import sys  
3  
4 if len(sys.argv) != 3:  
5     exit(f"Usage {sys.argv[0]} WORD WORD")  
6  
7 if is_anagram(sys.argv[1], sys.argv[2]):  
8     print("Anagram")  
9 else:  
10    print("NOT")
```

Solution: Testing demo

¹²¹<https://en.wikipedia.org/wiki/Anagram>

```
1  from anagram import is_anagram
2
3  def test_anagram():
4      assert is_anagram("silent", "listen")
5      assert is_anagram("bad credit", "debit card")
6
7  def test_not_anagram():
8      assert not is_anagram("abc", "def")
9
10 def test_should_be_anagram_spaces():
11     assert is_anagram("anagram", "nag a ram")
12
13
14 def test_should_be_anagram_case():
15     assert is_anagram("Silent", "Listen")
```

Testing Intro

The software testing equation

1 INPUT + PROCESS = EXPECTED_OUTPUT

The software testing equation (fixed)

1 INPUT + PROCESS = EXPECTED_OUTPUT + BUGS

The pieces of your software?

- Web application with HTML interface?
- Web application with HTML + JavaScript? Which frameworks?
- Web application with JSON interface? (API)
- What kind of databases do you have in the system? SQL? NoSQL? What size is the database?
- Source and the format of your input? Zip? CSV? XML? SQL Dump? JSON?
- The format of your output? HTML/PDF/CSV/JSON/XML/Excel/Email/..?
- Are you pushing out your results or are your clients pulling them? e.g. via an API?
- What external dependencies do you have? Slack, Twilio, What kind of APIs?

Manual testing

- How do you check your application now?

What to tests?

- Happy path
- Sad path
- Valid input
- Valid edge cases (0, -1, empty string, etc.)
- Broken input (string instead of number, invalid values, too long input, etc.)
- Extreme load
- System failure (power failure, network outage, lack of memory, lack of disk, ...)
- Third-party error or failure - How does your system work if the 3rd party API returns rubbish?

Continuous Integration

- Reduce feedback cycle
- Avoid regression
- On every push
- Every few hours full coverage

Functional programming

Functional programming

- Immutability (variables don't change)
- Separation of data and functions.
- First-class functions (you can assign function to another name and you can pass function to other functions and return them as well. We can also manipulate functions)
- Higher order functions: a functions that either takes a function as a parameter or returns a function as a parameter.

Iterators (Iterables)

You already know that there are all kinds of objects in Python that you can iterate over using the **for in** construct.

For example you can iterate over the characters of a string, or the elements of a list, or whatever **range()** returns.

You can also iterate over the lines of a file

and you have probably seen the **for in** construct in other cases as well. The objects that can be iterated over are collectively called

iterables^a.

You can do all kind of interesting things on such **iterables**. We'll see a few now.

^a<https://docs.python.org/3/glossary.html#term-iterable>

- A few data type we can iterate over using the **for ... in ...** construct. (strings, files, tuples, lists, list comprehension)

```
1 numbers = [101, 2, 3, 42]
2 for num in numbers:
3     print(num)
4 print(numbers)
5
6 print()
7
8 name = "FooBar"
9 for cr in name:
10     print(cr)
11 print(name)
12
13 print()
14
15 rng = range(3, 9, 2)
16 for num in rng:
17     print(num)
18 print(rng)
```

```
1 101
2 2
3 3
4 42
5 [101, 2, 3, 42]
6
7 F
8 o
9 o
10 B
11 a
12 r
13 FooBar
14
15 3
16 5
17 7
18 range(3, 9, 2)
```

range

So what does **range** really return?

Instead of returning the list of numbers (as it used to do in Python 2), now it returns a **range object** that provides “the opportunity to go over the specific series of numbers” without actually creating the **list** of numbers. Getting an object instead of the whole list has a number of advantages.

One is space. In the next example we’ll see how much memory is needed for the object returned by the **range** function and how much would it take to have the corresponding list of numbers in memory. For now let’s see how can we use it:

- `range(start, end, step)`
- `range(start, end)` - step defaults to 1
- `range(end)` - start defaults to 0, step defaults to 1

```
1  rng = range(3, 9, 2)
2  print(rng)
3  print(type(rng).__name__)
4
5  print()
6
7  for num in rng:
8      print(num)
9
10 print()
11
12 for num in rng:
13     print(num)
14
15 print()
16
17 print(rng[2])
```

```
1 range(3, 9, 2)
2 range
3
4 3
5 5
6 7
7
8 3
9 5
10 7
11
12 7
```

range with list

Using the **list** function we can tell the **range** object to generate the whole list immediately. Either using the variable that holds the **range** object, or wrapping the **range()** call in a **list()** call.

You might recall at the beginning of the course we saw the **sys.getsizeof()** function that returns the size of a Python object in the memory. If you don't recall, no problem, we'll see it used now. As you can see the size of the range object is only 48 bytes while the size of the 3-element list is already 112 bytes. It seems the range object is better than even such a short lists. On the next page we'll see a more detailed analysis.

```
1 import sys
2
3 rng = range(3, 9, 2)
4 numbers = list(rng)
5 print(rng)          # range(3, 9, 2)
6 print(numbers)      # [3, 5, 7]
7
8 others = list(range(2, 11, 3))
9 print(others)       # [2, 5, 8]
10
```

```

11 print(sys.getsizeof(rng))      # 48
12 print(sys.getsizeof(numbers)) # 112

```

range vs. list size

In this example we have a loop iterating over `range(21)`, but that's only for the convenience, the interesting part is inside the loop.

On every iteration call `range()` with the current number, then we convert the resulting object into a list of numbers. Finally we print out

the current number and the size of both the object returned by `range()` and the list generated from the object. As you can see the memory usage

of the `range` object remains the same 48 bytes, while the memory usage of the list grows as the list gets longer.

```

1 import sys
2
3 for ix in range(21):
4     rng = range(ix)
5     numbers = list(rng)
6     print("{:>3} {:>3} {:>4}".format(ix, sys.getsizeof(rng), sys.getsizeof(numbers)))

```

```

1      0  48   64
2      1  48   96
3      2  48  104
4      3  48  112
5      4  48  120
6      5  48  128
7      6  48  136
8      7  48  144
9      8  48  160
10     9  48  192
11    10  48  200
12    11  48  208
13    12  48  216
14    13  48  224
15    14  48  232
16    15  48  240
17    16  48  256
18    17  48  264

```

```
19 18 48 272
20 19 48 280
21 20 48 288
```

for loop with transformation

There are many cases when we have a list of some values and we need to apply some transformation to each value. At the end we would like to have the list of the resulting values.

A very simple such transformation would be to double each value. Other, more interesting examples might be reversing each string, computing some more complex function on each number, etc.)

In this example we just double the values and use **append** to add each value to the list containing the results.

```
1 def double(n):
2     return 2 * n
3
4 numbers = [1, 2, 3, 4]
5 name = "FooBar"
6
7 double_numbers = []
8
9 for num in numbers:
10     double_numbers.append( double(num) )
11 print(double_numbers)
12
13 double_letters = []
14 for cr in name:
15     double_letters.append( double(cr) )
16 print(double_letters)
```

```
1 [2, 4, 6, 8]
2 ['FF', 'oo', 'oo', 'BB', 'aa', 'rr']
```

There are better ways to do this.

map

- `map(function, iterable, ...)`

The `map`^a function of Python applies a function to every item in an iterable and returns an iterator that can be used to iterate over the results. Wow, how many times I repeated the word iter...something. Instead of trying to untangle that sentence, let's look at the following example:

^a<https://docs.python.org/library/functions.html#map>

We have a list of numbers in the brilliantly named variable `numbers` with 1, 2, 3, 4 as the content. We could like to create a list of all the doubles (so that would be 2, 4, 6, 8 in this case) and then iterate over them printing them on the screen. Sure, you probably have some more complex operation to do on the numbers than simply double them, but in this example I did not want to complicate that part. Suffice to say that you have some computation to do in every element.

So you encapsulate your computation in a regular Python function (in our case the function is called **double**). Then you call **map** and pass to it two parameters. The first parameter is the **double** function itself, the second parameter is the list of the values you would like to work on. `map` will go over all the values in the **numbers** list, call the **double** function with each number and provide allow you to iterate over the results. Something like this:

```
double_numbers = [ double(1), double(2), double(3), double(4)]
```

Except, that the above is not true.

When Python executes the `double_numbers = map(double, numbers)` line, no computation happens and no resulting list is created. Python only prepares “the possibility to do the computations”. In the upcoming examples we’ll see what does this sentence really mean, for now let’s see what do we have in this example: `double_numbers` contains a **map object**, but when you iterate over it using the **for num in double_numbers** construct you get the expected values.

In the second half of the example you can see the same works on strings as well.

```
1 def double(n):
2     return 2 * n
3
4 numbers = [1, 2, 3, 4]
5 name = "FooBar"
6
7 double_numbers = map(double, numbers)
8 print(double_numbers)    # <map object at 0x7f8eb2d849e8>
9 for num in double_numbers:
10     print(num)
11
12 double_letters = map(double, name)
13 print(double_letters)    # <map object at 0x7f8eb2d84cc0>
14 for cr in double_letters:
15     print(cr)
```

```
1 <map object at 0x7ff0c0d89da0>
2 2
3 4
4 6
5 8
6 <map object at 0x7ff0c0d89a20>
7 FF
8 oo
9 oo
10 BB
11 aa
12 rr
```

map delaying function call

In this example we have added a call to `print` in the `double` function in order to see when is it really executed. You can see that the first output comes from the `print` statement that was **after** the `map` call. Then on each iteration we see the output from inside the “double” function and then the result from the loop. In a nutshell Python does not execute the “double” function at the point where we called `map`. It only executes it when we iterate over the resulting object.

```
1 def double(n):
2     print(f"double {n}")
3     return 2 * n
4
5 numbers = [1, 4, 2, -1]
6
7 double_numbers = map(double, numbers)
8 print(double_numbers)
9
10 for num in double_numbers:
11     print(num)
```

```
1 <map object at 0x7f90df760f98>
2 double 1
3 2
4 double 4
5 8
6 double 2
7 4
8 double -1
9 -2
```

map on many values

Now imagine you have a very long list. I know this is not such a long list, but I trust you can imagine a long list of numbers. We would like to run some function on each element and then iterate over the results, but what if at one point in the iteration we decide to break out of the loop?

```
1 import sys
2
3 def double(n):
4     print(f"double {n}")
5     return 2 * n
6
7 numbers = [1, 4, 2, -1, 23, 12, 5, 6, 34, 143123, 98, 213]
8
9 double_numbers = map(double, numbers)
10 print(double_numbers)
11 for num in double_numbers:
12     print(num)
13     if num > 42:
14         break
15
16 print()
17 print(sys.getsizeof(numbers))
18 print(sys.getsizeof(double_numbers))
```

```
1 <map object at 0x7fe5c5270d68>
2 double 1
3 2
4 double 4
5 8
6 double 2
7 4
8 double -1
9 -2
10 double 23
11 46
12
13 160
14 56
```

You can see that it did not need to waste time calculating the doubles of all the values, as it was calculating on-demand. You can also see that the object returned from `map` takes up only 56 bytes. Regardless of the size of the original array.

map with list

Here too you can use the `list` function to convert all the values at once, but there is an advantage of keeping it as a **map object**. Not only the size that we already saw with the **range** case, but also the processing time saved by not calculating the results till you actually need it.

Imagine a case where you apply several expensive (time consuming) transformations to some original list and then you iterate over the end-results looking for the first value that matches some condition. What if you find the value you were looking for after only a few iteration. Then making all that expensive calculations to the whole list was a waste of time.

This lazy evaluation can help you save both memory and time and you always have the option to

force the immediate calculation by calling the **list** function.

```
1 def double(num):
2     return 2 * num
3
4 numbers = [1, 2, 3, 4]
5 name = "FooBar"
6
7 double_numbers = list(map(double, numbers))
8 print(double_numbers)
9
10 double_letters = list(map(double, name))
11 print(double_letters)
```

```
1 [2, 4, 6, 8]
2 ['FF', 'oo', 'oo', 'BB', 'aa', 'rr']
```

double with lambda

There are many other cases besides **map** where we need to pass a function as a parameter to some other function.

Many cases the function we pass is some almost trivial function with a single operation in it. In those cases creating a named function like the “double” function in the previous examples is an overkill.

In this example we also used the **list** function to force the full evaluation of the map object to make it easier to show the results. Normally you probably would not use the **list** function here.

```
1 numbers = [1, 2, 3, 4]
2 name = "FooBar"
3
4
5 double_numbers = list( map( lambda n: n * 2, numbers) )
6 print(double_numbers)
7
8
9 double_letters = map( lambda n: n * 2, name)
10 for cr in double_letters:
11     print(cr)
```

```
1 [2, 4, 6, 8]
2 FF
3 oo
4 oo
5 BB
6 aa
7 rr
```

What is lambda in Python?

Lambda creates simple anonymous function. It is simple because it can only have one statement in its body. It is anonymous because usually it does not have a name.

The usual use is as we saw earlier when we passed it as a parameter to the `map` function. However, in the next example we show that you can assign the lambda-function to a name and then you could use that name just as any other function you would define using `def`.

```
1 def dbl(n):  
2     return 2*n  
3 print(dbl(3))  
4  
5 double = lambda n: 2*n  
6 print(double(3))
```

```
1 6  
2 6
```

lambda returning tuple

A lambda function can return complex data structures as well. e.g. a tuple.

```
1 dbl = lambda n: (n, 2*n)  
2  
3 ret = dbl(12)  
4  
5 print(ret)
```

```
1 (12, 24)
```

map returning tuples

```
1 numbers = [1, 2, 3, 4]  
2  
3 pairs = map(lambda n: (n, 2*n), numbers)  
4 print(pairs)  
5  
6 for pair in pairs:  
7     print(pair)
```

```
1 <map object at 0x7fcd264a15f8>
2 (1, 2)
3 (2, 4)
4 (3, 6)
5 (4, 8)
```

lambda with two parameters

A **lambda**-function can have more than one parameters:

```
1 add = lambda x,y: x+y
2 print(add(2, 3))
```

```
1 5
```

map for more than one iterable

Lets “add” together two lists of numbers. Using + will just join the two lists together, but we can use the “map” function to add the values pair-wise.

```
1 v1 = [1, 3, 5, 9]
2 v2 = [2, 6, 4, 8]
3
4 v3 = v1 + v2
5 print(v3)
6
7 sums = map(lambda x,y: x+y, v1, v2)
8 print(sums)
9 print(list(sums))
```

```
1 [1, 3, 5, 9, 2, 6, 4, 8]
2 <map object at 0x7fcbecc8c668>
3 [3, 9, 9, 17]
```

map on uneven lists

In **Python 3** the iterator stops when the shortest iterable is exhausted.

In **Python 2** it used to extend the shorter lists by **None** values.

```
1 v1 = [1, 3, 5, 9]
2 v2 = [2, 6, 4, 8, 10]
3
4 sums = map(lambda x,y: x+y, v1, v2)
5 print(sums)
6
7 print(list(sums))
```

```
1 <map object at 0x7ff9469a8da0>
2 [3, 9, 9, 17]
```

replace None (for Python 2)

In Python 2 map used to extend the shorter lists by **None** values.

So to avoid exceptions, we had some extra code replacing the None values by 0, using the ternary operator.

```
1 v1 = [1, 3, 5, 9]
2 v2 = [2, 6, 4, 8, 10]
3
4 print(map(lambda x,y: (0 if x is None else x) + (0 if y is None else y), v1, v2))
5 # [3, 9, 9, 17, 10]
```

map on uneven lists - fixed (for Python 2)

A nicer fix was this:

```
1 v1 = [1, 3, 5, 9]
2 v2 = [2, 6, 4, 8, 10]
3
4 print(map(lambda x,y: (x or 0) + (y or 0), v1, v2))
5 # [3, 9, 9, 17, 10]
```

map mixed iterators

map works on any iterable, so we might end up passing one list and one string to it.

```
1 v1 = ['foo', 'bar', 'baz']
2 v2 = 'abc'
3
4 result = map(lambda x,y: x+y, v1, v2)
5 print(result)
6 print( list(result) )
```

```
1 <map object at 0x7fc5e9ff4e80>
2 ['fooa', 'barb', 'bazc']
```

map fetch value from dict

```
1 people = [
2     {
3         'name': 'Foo',
4         'phone': '123',
5     },
6     {
7         'name': 'Bar',
8         'phone': '456',
9     },
10    {
11        'name': 'SnowWhite',
12        'phone': '7-dwarfs',
13    }
14 ]
15
```

```
16 names = map(lambda d: d['name'], people)
17
18 print(names)
19 print(list(names))
```

```
1 <map object at 0x7f5afffaeb00>
2 ['Foo', 'Bar', 'SnowWhite']
```

Exercise: string to length

Given a list of strings, create an iterator that will provide the length of each string.

Exercise: row to length

Given a file, create an iterator that will provide the length of each row. Can you do it without actually reading the file?

Exercise: compare rows

Create an iterator that given two files will return true for each line where the first space in the first file is earlier than the first space in the second file. So

- given: “ab cd” vs “abc d” the value is true
- given: “ab cd” vs “ab cd” the value is false
- given: “ab cd” vs “a bcd” the value is false

Solution: string to length

```
1 animals = ['chicken', 'cow', 'snail', 'elephant', 'pig', 'zebra', 'gnu', 'praying ma\
2 ntiss', 'snake']
3
4 length = map(len, animals)
5 print(length)
6 print(list(length))
```

Solution: row to length

```

1 filename = __file__ # just being lazy and using ourselves as the input file
2
3 with open(filename) as fh:
4     length = map(len, fh)
5     print(length)
6     for ln in length:
7         print(ln)
8         # if ln > 10:
9         #     break

```

Solution: compare rows

```

1 import sys
2
3 file_a = 'map_string_to_len.py'
4 file_b = 'map_row_to_length.py'
5
6 def compare(row_a, row_b):
7     a = row_a.find(' ')
8     b = row_b.find(' ')
9     return a < b
10
11 with open(file_a) as fh_a, open(file_b) as fh_b:
12     results = map(compare, fh_a, fh_b)
13     print(results)
14     print(sys.getsizeof(results))
15
16     truth = list(results)
17     print(truth)
18     print(sys.getsizeof(truth))

```

```

1 <map object at 0x7f0858d3f8d0>
2 56
3 [False, True, False, True, True]
4 128

```

filter

- `filter(function, iterable)`

`filter` will return an iterable object that will return all the items of the original iterable that evaluate the function to **True**.
This can have only one iterable!

```
1 numbers = [1, 3, 27, 10, 38]
2 def big(n):
3     return n > 10
4
5 reduced = filter(big, numbers)
6 print(reduced)
7 print(list(reduced))
```

```
1 <filter object at 0x7f4bc37355c0>
2 [27, 38]
```

filter with lambda

```
1 numbers = [1, 3, 27, 10, 38]
2
3 reduced = filter(lambda n: n > 10, numbers)
4 print(reduced)
5 print(list(reduced))
```

```
1 <filter object at 0x7faed0fe57b8>
2 [27, 38]
```

filter - map example

```
1 numbers = [1, 7, 19, 5, 57, 23, 8]
2
3 def big(x):
4     print(f"filtering {x}")
5     return x > 10
6
7 def double(y):
8     print(f"double {y}")
9     return 2*y
10
11 big_numbers = filter(big, numbers)
12 print(big_numbers)
13
14 doubles = map(double, big_numbers)
15 print(doubles)
16
17 for num in doubles:
18     print(num)
```

```
1 <filter object at 0x7ffad9f82f28>
2 <map object at 0x7ffad9f829e8>
3 filtering 1
4 filtering 7
5 filtering 19
6 double 19
7 38
8 filtering 5
9 filtering 57
10 double 57
11 114
12 filtering 23
13 double 23
14 46
15 filtering 8
```

filter - map in one expression

```
1 numbers = [1, 7, 19, 5, 57, 23, 8]
2
3 def big(x):
4     print(f"filtering {x}")
5     return x > 10
6
7 def double(y):
8     print(f"double {y}")
9     return 2*y
10
11
12 for num in map(double, filter(big, numbers)):
13     print(num)
```

```
1 filtering 1
2 filtering 7
3 filtering 19
4 double 19
5 38
6 filtering 5
7 filtering 57
8 double 57
9 114
10 filtering 23
11 double 23
12 46
13 filtering 8
```

Get indexes of values

`filter` can help us get a sublist of values from an iterable, eg. from a list that match some condition. In this example we see how to get all the names that are exactly 3 characters long.

What if, however if instead of the values themselves, you would like to know their location? The indexes of the places where these value can be found. In that case, you would run the `filter` on the indexes from 0 till the last valid index of the list. You can do that using the `range` function.

Finally there is another example that shows how to get the indexes of all the names that have an “e” in them.
Just to show you that we can use any arbitrary condition there.

```

1 names = ["Helen", "Ann", "Mary", "Harry", "Joe", "Peter"]
2 names3 = filter(lambda w: len(w) == 3, names)
3 print( list(names3) )
4
5 loc3 = filter(lambda i: len(names[i]) == 3, range(len(names)))
6 print( list(loc3) )
7
8
9 has_e = filter(lambda i: "e" in names[i], range(len(names)))
10
11 print( list(has_e) )

```

```

1 ['Ann', 'Joe']
2 [1, 4]
3 [0, 4, 5]

```

reduce

In Python 2 it was still part of the language.

```
reduce(function, iterable[, initializer])
```

```

1 from functools import reduce
2
3 numbers = [1, 2, 3, 4]
4
5 print(reduce(lambda x,y: x+y, numbers))    # 10 = ((1+2)+3)+4
6 print(reduce(lambda x,y: x*y, numbers))    # 24 = ((1*2)*3)*4
7 print(reduce(lambda x,y: x/y, [8, 4, 2]))  # 1.0
8
9 print(reduce(lambda x,y: x+y, [2]))        # 2

```

```

10 print()
11
12 # print(reduce(lambda x,y: x+y, []))
13     # TypeError: reduce() of empty sequence with no initial value
14 print(reduce(lambda x,y: x+y, [], 0))      # 0
15 print(reduce(lambda x,y: x+y, [2,4], 1))   # 7
16 print()
17
18 mysum = 0
19 for num in numbers:
20     mysum += num
21 print(mysum)          # 10
22
23 mymultiple = 1
24 for num in numbers:
25     mymultiple *= num
26 print(mymultiple)     #24

```

```

1  10
2  24
3  1.0
4  2
5
6  0
7  7
8
9  10
10 24

```

The initializer is used as the 0th element returned by the iterable. It is mostly interesting in case the iterable is empty.

reduce with default

```

1  from functools import reduce
2
3  print( reduce(lambda x,y: x+y, [], 0) )      # 0
4  print( reduce(lambda x,y: x+y, [1, 2], 0) )  # 3
5
6  print( reduce(lambda x,y: x*y, [1, 2], 0) )  # 0
7  print( reduce(lambda x,y: x*y, [2, 3], 1) )  # 6
8  print( reduce(lambda x,y: x*y, [], 0) )      # 0

```

```

1  0
2  3
3  0
4  6
5  0

```

zip

```

1  fname = ['Graham',      'Eric',      'Terry',
2           'Terry',      'John',      'Michael']
3  lname = ['Chapman',     'Idle',      'Gilliam',
4           'Jones',      'Cleese',    'Palin']
5  born  = ['8 January 1941', '29 March 1943', '22 November 1940',
6           '1 February 1942', '27 October 1939', '5 May 1943']
7
8  for f_name, l_name, b_date in zip(fname, lname, born):
9      print("{:10} {:10} was born {}".format(f_name, l_name, b_date))

```

```

1  Graham      Chapman      was born 8 January 1941
2  Eric        Idle         was born 29 March 1943
3  Terry       Gilliam      was born 22 November 1940
4  Terry       Jones        was born 1 February 1942
5  John        Cleese       was born 27 October 1939
6  Michael     Palin        was born 5 May 1943

```

Monty Python¹²⁵

Creating dictionary from two lists using zip

¹²⁵https://en.wikipedia.org/wiki/Monty_Python

```
1 names = ['Jan', 'Feb', 'Mar', 'Apr']
2 days = [31, 28, 31, 30]
3
4 zipped = zip(names, days)
5 print(zipped)
6
7 pairs = list(zipped)
8 print(pairs)
9
10 month = dict(zipped)
11 print(month)    # this is empty because zipped was already exhausted by the "list" call
12 ll
13
14 zipped = zip(names, days)
15 month = dict(zipped)
16 print(month)

1 <zip object at 0x7ff021949788>
2 [('Jan', 31), ('Feb', 28), ('Mar', 31), ('Apr', 30)]
3 {}
4 {'Jan': 31, 'Feb': 28, 'Mar': 31, 'Apr': 30}
```

all, any

- `all(iterable)` - returns True if all the elements of iterable return True
- `any(iterable)` - returns True if any of the elements in iterable return True

```
1 a = [True, True]
2 b = [True, False]
3 c = [False, False]
4
5 print(all(a))    # True
6 print(all(b))    # False
7 print(all(c))    # False
8 print()
9 print(any(a))    # True
10 print(any(b))    # True
11 print(any(c))    # False
```

Compare elements of list with scalar

```
1 print(2 > 1) # True
2 print(0 > 1) # False
3 print()
4
5 numbers = [2, 4]
6 # Comparing different types does not make sense, but nevertheless Python 2 would sti\
7 ll do it.
8 # Python 3 raises exception:
9 # TypeError: '>' not supported between instances of 'list' and 'int'
10 # print(numbers > 1) # True
11 # print(numbers > 7) # True
12 # print()
13
14 # compare each element with the scalar and then check if 'all' were True
15 print(all(map(lambda x: x > 1, numbers))) # True
16 print(all(map(lambda x: x > 2, numbers))) # False
```

List comprehension - double

We take the original example where we had a function called double, and this time we write a different expression to run the function on every element of an iterable.

```
1 def double(n):
2     return 2*n
3
4 numbers = [1, 2, 3, 4]
5 name = "FooBar"
6
7 double_numbers = [double(n) for n in numbers]
8 print(double_numbers) # [2, 4, 6, 8]
9
10
11 double_chars = [double(n) for n in name]
12 print(double_chars) # ['FF', 'oo', 'oo', 'BB', 'aa', 'rr']
```

List comprehension - simple expression

```
1  import sys
2
3  numbers = [0, 1, 2, 3]
4
5  sqrs = map(lambda n: n*n, numbers)
6  print(sqrs)           # <map object at 0x7fdcab2f5940>
7  print(list(sqrs))     # [0, 1, 4, 9]
8  print(sys.getsizeof(sqrs))
9  print()
10
11 squares = [n*n for n in numbers]
12 print(squares)        # [0, 1, 4, 9]
13 print(sys.getsizeof(squares))
```

```
1  <map object at 0x7fa9cf2eb9e8>
2  [0, 1, 4, 9]
3  56
4
5  [0, 1, 4, 9]
6  96
```

List generator

Going over the values of the generator will empty the generator.

```
1  import sys
2
3  numbers = [0, 1, 2, 3, 4, 5, 6]
4
5  gn = (n*n for n in numbers)
6  print(gn)
7  print(sys.getsizeof(gn))
8  print()
9
10 for num in gn:
11     print(num)
12 print()
13
14 gn = (n*n for n in numbers)
15 squares = list(gn)
16 print(sys.getsizeof(squares))
```

```
17 print(squares)
18
19 print(list(gn)) # the generator was already exhausted
```

```
1 <generator object <genexpr> at 0x7f8c0bda2930>
2 120
3
4 0
5 1
6 4
7 9
8 16
9 25
10 36
11
12 160
13 [0, 1, 4, 9, 16, 25, 36]
14 []
```

List comprehension

```
1 text = ['aaaa', 'bb', 'ccc ccc']
2
3 length_1 = map(lambda x: len(x), text)
4 print(length_1)          # <map object at 0x7f60ceb90f98>
5 print(list(length_1))    # [4, 2, 7]
6
7
8 length_2 = map(len, text)
9 print(length_2)          # <map object at 0x7f60ceb90fd0>
10 print(list(length_2))    # [4, 2, 7]
11
12
13 length_3 = [ len(s) for s in text ]
14 print(length_3)          # [4, 2, 7]
```

In LISP this would be a `mapcar`.

Dict comprehension

```
1 people = {
2     'Foo':      123,
3     'Bar':      456,
4     'SnowWhite': 7,
5 }
6
7 doubles = { k:v*2 for (k, v) in people.items() }
8 print(doubles) # {'Foo': 246, 'Bar': 912, 'SnowWhite': 14}
```

Lookup table with lambda

```
1 import sys
2
3 table = {
4     "cat" : lambda : print("miau"),
5     "dog" : lambda : print("hauhau"),
6     "duck" : lambda : print("hap hap"),
7 }
8
9
10 def main():
11     if len(sys.argv) != 2:
12         exit(f"Usage: {sys.argv[0]} NAME")
13
14     animal = sys.argv[1]
15     if animal in table:
16         table[animal]()
17
18 main()
```

Read lines without newlines

```
1 import sys
2
3 if len(sys.argv) != 2:
4     exit(f"Usage: {sys.argv[0]}")
5
6 filename = sys.argv[1]
7
8 with open(filename) as fh:
9     rows = map(lambda s: s.rstrip("\n"), fh.readlines())
10
11 for row in rows:
12     print(row)
```

Read key-value pairs

```
1 name=Foo Bar
2 email=foo@bar.com
3 address=Foo street 42
```

```
1 import sys
2
3 if len(sys.argv) != 2:
4     exit(f"Usage: {sys.argv[0]}")
5
6 filename = sys.argv[1]
7
8 with open(filename) as fh:
9     pairs = dict(map(lambda x: x.split('='), map(lambda s: s.rstrip("\n"), fh.readlines())))
10
11
12 print(pairs)
```

```
1 {'name': 'Foo Bar', 'email': 'foo@bar.com', 'address': 'Foo street 42'}
```

Create index-to-value mapping in a dictionary based on a list of values

```

1 planned_order = ('b', 'c', 'd', 'a')
2 plan = dict(zip(range(len(planned_order)), planned_order))
3 print(plan)

```

```

1 {0: 'b', 1: 'c', 2: 'd', 3: 'a'}

```

Exercise: min, max, factorial

- Implement an expression to calculate “min”, and another expression to calculate “max” of lists.
- Implement an expression that will calculate factorial. $f(n)$ should return the value of $n!$ ($n! = n * (n-1) * (n-2) * \dots * 1$)
- Implement an expression that given 2 lists will return a new list in which each element is the `max()` for each pair from the input lists. E.g. given `[1, 3, 6]` and `[2, 4, 5]` the result is `[2, 4, 6]`
- Use `reduce`, `map`, `lambda`

Exercise: Prime numbers

Calculate and print the prime numbers between 2 and N. Use `filter`.

Exercise: Many validator functions

Given several validator functions (that get a parameter and return True or False), and given a list of values, return a sublist of values that pass all the validation checks. See the skeleton:

```

1 def is_big(x):
2     return x > 100
3
4 def is_even(x):
5     return not x % 2
6
7 numbers = [90, 102, 101, 104]
8
9 cond = [is_big, is_even]
10
11 # z = ...
12 print(z) # [102, 104]

```

Exercise: Calculator using lookup table

Write a script that will accept a math expression such as `python calc.py 2 + 3` and will print the result.

Use lookup tables select the implementation of the actual computation. (supporting `+`, `-`, `*`, `/`) is enough

Exercise: parse file

In the following file we have lines:

```
1 SOURCE/FILENAME.json,TARGET
```

read in the file and create

- a single dictionary where the `SOURCE/FILENAME.json` is the key and the `TARGET` is the value.
- list of dictionaries in which the keys are `'source'`, `'filename'`, and `'target'` and the values are from the respective columns (`SOURCE`, `FILENAME.json`, and `TARGET`)

You can solve this `for`-loop or with `map` and list-comprehensions. Do it in both ways.

```

Solution: min, max, factorial

```
1 from functools import reduce
2
3 numbers = [2, 1, 4, 3]
4
5 # min
6 print(reduce(lambda x,y: x if x < y else y, numbers)) # 1
7 # max
8 print(reduce(lambda x,y: x if x > y else y, numbers)) # 4
9
10 # factorial
11 n = 4
12 print(reduce(lambda x,y: x*y, range(1, n+1), 1)) # 24
13 # The 1 at the end is the initializor of reduce to provide
```

```
14 # correct results for n = 0.
15
16 a = [1, 3, 6]
17 b = [2, 4, 5]
18 c = map(lambda x,y: x if x > y else y, a, b)
19 print(list(c)) # [2, 4, 6]
```

Solution: Prime numbers

Calculating the prime numbers

```
1 n = 50
2
3 nums = range(2, n)
4 for i in range(2, 1+int(n**0.5)):
5     nums = filter(lambda x: x == i or x % i, nums)
6
7 print(nums)
```

Solution: Many validator functions

```
1 def is_big(x):
2     return x > 100
3
4 def is_even(x):
5     return not x % 2
6
7 numbers = [90, 102, 101, 104]
8
9 cond = [is_big, is_even]
10
11 z = filter(lambda n: all([f(n) for f in cond]), numbers)
12 print(z) # [102, 104]
```

Solution: Calculator using lookup table

```
1  import sys
2
3  table = {
4      "+" : lambda x, y: x+y,
5      "-" : lambda x, y: x-y,
6      "*" : lambda x, y: x*y,
7      "/" : lambda x, y: x/y,
8  }
9
10
11 def main():
12     if len(sys.argv) != 4:
13         exit(f"Usage: {sys.argv[0]} NUMBER OP NUMBER")
14     action = table[sys.argv[2]]
15     print( action(int(sys.argv[1]), int(sys.argv[3])) )
16
17 main()
```

map with condtion

The conversion function can do anything. It can have a condition inside.

```
1  numbers = [1, 2, 3, 4]
2
3  def cond_double(n):
4      if n % 2:
5          return 2*n
6      else:
7          return n
8
9  cd = map(cond_double, numbers)
10 print(cd)                # [2, 2, 6, 4]
```

map with lambda

```
1 numbers = [1, 2, 3, 4]
2
3 def dbl(x):
4     return 2*x
5 d1 = map(dbl, numbers)
6 print(d1) # [2, 4, 6, 8]
7
8 double = lambda x: 2*x
9 d2 = map(double, numbers)
10 print(d2) # [2, 4, 6, 8]
11
12 d3 = map(lambda n: 2*n, numbers)
13 print(d3) # [2, 4, 6, 8]
```

map with lambda with condition

```
1 numbers = [1, 2, 3, 4]
2
3 a = map(lambda n: 2*n if n % 2 else n, numbers)
4 print(a) # [2, 2, 6, 4]
```

List comprehension - complex

```
1 numbers = [1, 3, 2, 4]
2
3 t = filter(lambda n: n > 2, numbers)
4 print(t) # [3, 4]
5
6 n1 = map(lambda n: n*n, t)
7 print(n1) # [9, 16]
8
9
10 n2 = map(lambda n: n*n, filter(lambda n: n > 2, numbers))
11 print(n2) # [9, 16]
12
13
14
15 n3 = [ n*n for n in numbers if n > 2 ]
16 print(n3) # [9, 16]
```

Iterators - with and without Itertools

Advantages of iterators and generators

- Lazy evaluation
- Save processing (or at least delay the use)
- Save memory
- Handle an infinite series of information
- Turn complex operations into a simple matter of `for` loop.

The Fibonacci research institute

- We have a bunch of mathematicians who research the Fibonacci series.
- We have a bunch of people who research a series of DNA sequences.
- ???

Fibonacci plain

- We don't call this as this has an infinite loop

```
1 def fibonacci():
2     a, b = 0, 1
3     while True:
4         a, b = b, a+b
5
6 # fibonacci()
```

Fibonacci copy-paste

```
1 def fibonacci():
2     a, b = 0, 1
3     while True:
4         a, b = b, a+b
5
6         print(a)
7         if a % 17 == 0:
8             print('found')
9             break
10
11         if a > 200:
12             print('not found')
13             break
14
15 fibonacci()
```

Iterators Glossary

- [iterable](#)¹²⁶ (Can be iterated over using a for loop.)
- [iterator](#)¹²⁷
- Every iterator is also iterable
- Iterators (and iterables) are not necessarily addressable like lists with the `thing[index]` construct.
- [Iterator Types](#)¹²⁸
- [The standard type hierarchy](#)¹²⁹

What are iterators and iterables?

- All of them are iterables
- A filehandle and the map object are also iterators. (Side note: You should always open files using the `with` statement and not like this.)
- `iter()` would return the iterator from an iterable. We don't need this.

¹²⁶<https://docs.python.org/glossary.html#term-iterable>

¹²⁷<https://docs.python.org/glossary.html#term-iterator>

¹²⁸<https://docs.python.org/library/stdtypes.html#typeiter>

¹²⁹<https://docs.python.org/reference/datamodel.html#types>

```

1  from collections.abc import Iterator, Iterable
2
3  a_string = "Hello World"
4  a_list   = ["Tiger", "Mouse"]
5  a_tuple  = ("Blue", "Red")
6  a_range  = range(10)
7  a_fh     = open(__file__)
8  a_map     = map(lambda x: x*2, a_list)
9
10 for thing in [a_string, a_list, a_tuple, a_range, a_map, a_fh]:
11     print(thing.__class__.__name__)
12     print(issubclass(thing.__class__, Iterator))
13     print(issubclass(thing.__class__, Iterable))
14     zorg = iter(thing)
15     print(zorg.__class__.__name__)
16     print(issubclass(zorg.__class__, Iterator))
17
18     print()
19
20 a_fh.close()

```

```

26 True
27 True
28 TextIOWrapper
29 True
```

A file-handle is an iterator

This slightly a repetition of the previous statement, that filehandles are iterators.

```
1 from collections.abc import Iterator, Iterable
2 from io import TextIOWrapper
3
4 with open(__file__) as fh:
5     print(fh.__class__.__name__)
6     print(issubclass(fh.__class__, TextIOWrapper))
7     print(issubclass(fh.__class__, Iterator))
8     print(issubclass(fh.__class__, Iterable))
9
10    for line in fh:
11        pass
12        #print(line, end="")
```

```
1 TextIOWrapper
2 True
3 True
4 True
```

range is iterable but it is not an iterator

Just as a string or a list, the range function in Python is also an “iterable” but it is not an “iterator”. In many aspects it behaves as an iterator. Specifically it allows us to iterate over numbers.

Range Is Not An Iterator^a

^a<https://treyhunner.com/2018/02/python-range-is-not-an-iterator/>

- `range`¹³⁰

```
1  for n in range(2, 12, 3):
2      print(n)
3  print()
4
5  for n in range(3):
6      print(n)
7  print()
8
9  for n in range(2, 5):
10     print(n)
11 print()
12
13 from collections.abc import Iterator, Iterable
14 rng = range(2, 5)
15 print(issubclass(rng.__class__, Iterator))
16 print(issubclass(rng.__class__, Iterable))
```

```
1  2
2  5
3  8
4  11
5
6  0
7  1
8  2
9
10 2
11 3
12 4
13
14 False
15 True
```

¹³⁰<https://docs.python.org/library/functions.html#func-range>

Iterator: a counter

We can create a iterator using a class. We are required to implement the `__iter__` method that returns the iterator object and the `__next__` method that returns the next element in our iteration. We can indicated that the iteration was exhausted by raising a `StopIteration` exception.

The instance-object that is created from this class-object is the iterator, not the class-object itself!

- `__iter__`
- `__next__` (in Python 2 this used to called `next`)
- `raise StopIteration`

```
1 class Counter():
2     def __init__(self):
3         self.count = 0
4
5     def __iter__(self):
6         return self
7
8     def __next__(self):
9         self.count += 1
10        if self.count > 3:
11            raise StopIteration
12        return self.count
```

Using iterator

The class returned an iterator, we could use a for loop to iterate over the element. We tried to run through the iterator again, but it did not print anything. It was exhausted.

```
1 from counter import Counter
2
3 cnt = Counter()
4 for c in cnt:
5     print(c)
6
7 for c in cnt:
8     print(c)
```

```
1 1
2 2
3 3
```

Iterator without temporary variable

```
1 from counter import Counter
2
3 for c in Counter():
4     print(c)
```

```
1 1
2 2
3 3
```

The type of the iterator

How can we know it is an iterator? We check it.

```
1 from collections.abc import Iterator, Iterable
2 from counter import Counter
3
4 cnt = Counter()
5 print(cnt.__class__.__name__)
6 print(issubclass(cnt.__class__, Iterator))
7 print(issubclass(cnt.__class__, Iterable))
```

```
1 Counter
2 True
3 True
```

Using iterator with next

A feature of any iterator is that we could iterate over it using the next call.

```
1 from counter import Counter
2
3 cnt = Counter()
4
5 while True:
6     try:
7         a = next(cnt)
8         print(a)
9     except Exception as ex:
10        print(ex.__class__.__name__)
11        break
```

```
1 1
2 2
3 3
4 StopIteration
```

Mixing for and next

You can even use `next` inside a `for` loop, but then you will have to handle the `StopIteration` exception that might happen during your call of `next`.

I am not really sure when would we want to use this.

```
1  from counter import Counter
2
3  cnt = Counter()
4
5  for i in cnt:
6      print(f"i: {i}")
7      try:
8          n = next(cnt)
9          print(f"n: {n}")
10     except Exception as ex:
11         print(ex.__class__.__name__)
12         break
```

```
1  i: 1
2  n: 2
3  i: 3
4  StopIteration
```

Iterable which is not an iterator

```
1  from counter import Counter
2
3  class GetMyIterable():
4      def __init__(self):
5          pass
6      def __iter__(self):
7          return Counter()
8
9
10 thing = GetMyIterable()
11
12 from collections.abc import Iterator, Iterable
13 print(issubclass(thing.__class__, Iterator))
```

```
14 print(issubclass(thing.__class__, Iterable))
15
16 for i in thing:
17     print(i)
```

```
1 False
2 True
3 1
4 2
5 3
```

Iterator returning multiple values

```
1 class SquareCounter():
2     def __init__(self):
3         self.count = 0
4
5     def __iter__(self):
6         return self
7
8     def __next__(self):
9         self.count += 1
10        if self.count > 5:
11            raise StopIteration
12        return self.count, self.count ** 2
13
14 for cnt, sqr in SquareCounter():
15     print(f'{cnt} {sqr}')
```

```
1 1 1
2 2 4
3 3 9
4 4 16
5 5 25
```

Range-like iterator

```

1  class Range():
2      def __init__(self, start, end):
3          self.current = start
4          self.end = end
5
6      def __iter__(self):
7          return self
8
9      def __next__(self):
10         if self.current >= self.end:
11             raise StopIteration
12         v = self.current
13         self.current += 1
14         return v

```

```

1  import it
2
3  r = it.Range(1, 4)
4  for n in r:
5      print(n)
6
7  print('---')
8
9  for n in it.Range(2, 5):
10     print(n)

```

```

1  1
2  2
3  3
4  ---
5  2
6  3
7  4

```

Unbound or infinite iterator

So far each iterator had a beginning and an end. However we can also create infinite or unbounded iterators.

The nice thing about them is that we can pass them around as we do with any other object and we can execute

operations on them without burning our CPU.

Of course the user will have to be careful not to try to flatten the iterator, not to try to get all the values

from it, as that will only create an infinite loop or a never ending operation.

In this very simple example we count from 0 and we never stop.

When we use the `Counter` in the `for` loop we need to include a stop-condition, otherwise our loop will never end.

```
1 class Counter():
2     def __init__(self):
3         self.count = 0
4
5     def __iter__(self):
6         return self
7
8     def __next__(self):
9         self.count += 1
10        return self.count
11
12 for c in Counter():
13     print(c)
14     if c > 10:
15         break
```

```
1 1
2 2
3 3
4 4
5 5
6 6
7 7
8 8
9 9
10 10
11 11
```

Unbound iterator Fibonacci

Now we can get back to our original problem, the slightly more complex Fibonacci series. In this example we created an unbounded iterator that on every iteration will return the next element of the Fibonacci series.

```
1 class Fibonacci():
2     def __init__(self):
3         self.values = []
4
5     def __iter__(self):
6         return self
7
8     def __next__(self):
9         if len(self.values) == 0:
10             self.values.append(1)
11             return 1
12
13         if len(self.values) == 1:
14             self.values.append(1)
15             return 1
16
17         self.values.append(self.values[-1] + self.values[-2])
18         self.values.pop(0)
19
20         return self.values[-1]
```

```
1 from fibonacci import Fibonacci
2 for v in Fibonacci():
3     print(v)
4     if v > 10:
5         break
```

```
1 1
2 1
3 2
4 3
5 5
6 8
7 13
```

Operations on Unbound iterator

```
1 from fibonacci import Fibonacci
2
3 fib = Fibonacci()
4
5 #odd = [x for x in fib if x % 2 == 1]
6 odd = filter(lambda x: x % 2 == 1, fib)
7
8 print("Let's see")
9
10 for v in odd:
11     print(v)
12     if v > 10:
13         break
```

```
1 Let's see
2 1
3 1
4 3
5 5
6 13
```

itertools

- [itertools](http://docs.python.org/library/itertools.html)¹³¹

¹³¹<http://docs.python.org/library/itertools.html>

itertools is a standard Python library that provides a number of interesting iterators. We are going to see a few examples here:

itertools - count

- Unbound counter: Count from N to infinity.

```
1  import itertools
2
3  for c in itertools.count(start=19, step=1):
4      print(c)
5      if c > 23:
6          break
7
8  # 19
9  # 20
10 # 21
11 # 22
12 # 23
13 # 24
```

itertools - cycle

```
1  import itertools
2
3  ix = 0
4  for c in itertools.cycle(['A', 'B', 'C']):
5      print(c)
6      ix += 1
7      if ix >= 5:
8          break
9
10 print('')
11
12 ix = 0
13 for c in itertools.cycle('DEF'):
14     print(c)
```

```
15     ix += 1
16     if ix >= 5:
17         break
```

```
1  A
2  B
3  C
4  A
5  B
6
7  D
8  E
9  F
10 D
11 E
```

Exercise: iterators - reimplement the range function

In one of the first slides of this chapter we saw a partial implementation of the range function. Change that code to have a full implementation, that can accept 1, 2, or 3 parameters.

Exercise: iterators - cycle

- Reimplement the cycle functions of itertools using iterator class.

Exercise: iterators - alter

- Implement the alter functions as an iterator that will return

```
1  1
2  -2
3  3
4  -4
5  5
6  -6
7  ...
```

- Optionally provide a start and end parameters
- start defaults to 1
- end defaults to unlimited

Exercise: iterators - limit Fibonacci

Change the Iterator version of the Fibonacci series so optionally you will be able to provide a parameter called “limit” to the constructor. If the limit is provided, the iterator should stop when the value passes the limit.

Exercise: iterators - Fibonacci less memory

Change the Iterator version of the Fibonacci series so it will NOT hold the previous values in memory.

Exercise: read char

Create an iterator that given a filename will return an object that on every iteration will return a single character. As an option let the user skip newlines, or maybe any pre-defined character.

Exercise: read section

- Create an iterator that given the name of a file like the following, will return once section at a time.
- It will return a list one each iteration and each element of the list will be a line from the current section.
- Other ideas what should be returned on each iteration?

```
1  name      = Mercury
2  distance  = 0.4
3  mass      = 0.055
4
5
6  name      = Venus
7  distance  = 0.7
8  mass      = 0.815
9
10
11 name      = Earth
12 distance  = 1
13 mass      = 1
14
15 name      = Mars
16 distance  = 1.5
17 mass      = 0.107
```

Exercise: collect packets

- You get a series of packets (e.g. lines in a file)
- In each line you have several fields: id, seqid, maxseq, content
- id is a unique identifier of a series of packets (lines)
- seqid is the sequence id of a packet in a series. (an integer)
- maxseq is the length of the sequence.
- content is the actual content.

In each iteration return a message that is built up from all the packages in the given sequence.

```

1 12,1,5,First of Twelve
2 12,2,5,Second of Twelve
3 12,3,5,Third of Twelve

Exercise: compare files

Compare two files line-by-line, and create a 3rd file listing the lines that are different.

```
1 One
2 Two
3 Three
4 Four
5 Five
```

```
1 One
2 Two
3 Tree
4 Four
5 Five
```

Expected output:

```
1 2, Three, Tree
```

Solution: iterators - limit Fibonacci

```
1 class Fibonacci:

27
28
29 filename = 'planets.txt'
30 for sec in SectionReader(filename):
31     print(sec)
```

Solution: compare files

```

1  import sys
2
3  def main():
4      if len(sys.argv) != 4:
5          exit(f"Usage: {sys.argv[0]} IN_FILE IN_FILE OUT_FILE")
6      infile_a, infile_b = sys.argv[1:3]
7      outfile = sys.argv[3]
8
9      with open(outfile, 'w') as out_fh, open(infile_a) as in_a, open(infile_b) as in_
10 b:
11         cnt = 0
12         for lines in zip(in_a, in_b):
13             #print(lines)
14             lines = list(map(lambda s: s.rstrip('\n'), lines))
15             #print(lines)
16             if lines[0] != lines[1]:
17                 out_fh.write(f"{cnt},{lines[0]},{lines[1]}\n")
18                 cnt += 1
19
20 main()

```

```
1 python diff.py first.txt second.txt diff.txt
```

Solution: collect packets

The implementation

```

1  class Packets():
2      def __init__(self, filename):
3          self.filename = filename
4          self.fh = open(filename)
5          self.packets = {}
6          self.max = {}
7
8      def __iter__(self):
9          return self
10
11     def __next__(self):
12         while True:
13             line = self.fh.readline()
14             #print(f"line: {line}")

```

```

15         if line == '':
16             raise StopIteration
17
18         line = line.rstrip("\n")
19         if line == '':
20             continue
21
22         pid, seqid, maxseq, content = line.split(",")
23         pid = int(pid)
24         seqid = int(seqid)
25         maxseq = int(maxseq)
26         if pid not in self.packets:
27             self.packets[pid] = {}
28             self.max[pid] = maxseq
29         if seqid in self.packets[pid]:
30             raise Exception("pid arrived twice")
31         if maxseq != self.max[pid]:
32             raise Exception("maxseq changed")
33         self.packets[pid][seqid] = content
34         if len(self.packets[pid].keys()) == self.max[pid]:
35             content = list(map(lambda i: self.packets[pid][i+1], range(self.max[\
36 pid])))
37             del(self.max[pid])
38             del(self.packets[pid])
39             return content

```

The use:

```

1  import sys
2  from packets import Packets
3
4  if len(sys.argv) < 2:
5      exit(f"Usage: {sys.argv[0]} FILENAME")
6
7  for packet in Packets(sys.argv[1]):
8      print(packet)

```

The test to verify it

```
1  import os
2  import json
3  import pytest
4
5  from packets import Packets
6
7  root = os.path.dirname(os.path.abspath(__file__))
8
9  with open(os.path.join(root, 'packets.json')) as fh:
10     expected_results = json.load(fh)
11
12  @pytest.mark.parametrize('filename', ['packets.txt', 'packets1.txt', 'packets2.txt'])
13  def test_packetes(filename):
14     filepath = os.path.join(root, filename)
15
16     results = []
17     for packet in Packets(filepath):
18         results.append(packet)
19     assert results == expected_results
```

Expected result:

```
1  ["First of Twelve", "Second of Twelve", "Third of Twelve", "Fourth of Twelve", "Fif\
2  th of Twelve"], ["First of Nine", "Second of Nine", "Third of Nine", "Fourth of Nine\
3  "], ["First of Eleven", "Second of Eleven", "Third of Eleven"]]
```

Generators and Generator Expressions

Generators Glossary

- [generator](#)¹³² (a function that returns a “generator iterator”)
 - [generator-iterator](#)¹³³ (an object created by a generator)
 - [Generator types](#)¹³⁴
 - [generator-expression](#)¹³⁵
- Generators are basically a way to create iterators without a class.

Iterators vs Generators

- a generator is an iterator
- an iterator is an iterable

```
1 from collections.abc import Iterator, Iterable
2 from types import GeneratorType
3
4 print(issubclass(GeneratorType, Iterator)) # True
5 print(issubclass(Iterator, Iterable))     # True
```

- Generators are a simpler way to create an iterable object than iterators, but iterators allow for more complex iterables.
- To create an iterator we need a class with two methods: `__iter__` and `__next__`, and a `raise StopIteration`.
- To create a generator we only need a single function with `yield`.

List comprehension and Generator Expression

¹³²<https://docs.python.org/glossary.html#term-generator>

¹³³<https://docs.python.org/glossary.html#term-generator-iterator>

¹³⁴<https://docs.python.org/library/stdtypes.html#generator-types>

¹³⁵<https://docs.python.org/glossary.html#term-generator-expression>

However, before learning about `yield` let's see an even simpler way to create a generator. What we call a generator expression.

You are probably already familiar with list comprehensions where you have a `for` expression inside square brackets. That returns a `list` of values.

If you replace the square brackets with parentheses then you get a **generator expression**.

You can iterate over either of those. So what's the difference?

```
1 a_list = [i*2 for i in range(3)]
2 print(a_list)
3 for x in a_list:
4     print(x)
5 print()
6
7 a_generator = (i*2 for i in range(3))
8 print(a_generator)
9 for x in a_generator:
10     print(x)
```

```
1 [0, 2, 4]
2 0
3 2
4 4
5
6 <generator object <genexpr> at 0x7f0af6f97a50>
7 0
8 2
9 4
```

List comprehension vs Generator Expression - less memory

Let's use a bigger range of numbers and create the corresponding list and generator. Then check the size of both of them.

You can see the list is much bigger. That's because the list already contains all the elements, while the generator contains only the promise to give you all the elements.

As we could see in the previous example, this is not an empty promise, you can indeed iterate over the elements of a generator just as you can iterate over the elements of a list.

However, you cannot access an arbitrary element of a generator because the generator is not subscriptable.

```
1  import sys
2
3  lst = [n*2 for n in range(1000)] # List comprehension
4  gen = (n*2 for n in range(1000)) # Generator expression
5
6  print(sys.getsizeof(lst))
7  print(sys.getsizeof(gen))
8  print()
9
10 print(type(lst))
11 print(type(gen))
12 print()
13
14 print(lst[4])
15 print()
16
17 print(gen[4])
```

```
1  9016
2  112
3
4  <class 'list'>
5  <class 'generator'>
6
7  8
8
9  Traceback (most recent call last):
10   File "generator_expression.py", line 17, in <module>
11     print(gen[4])
12  TypeError: 'generator' object is not subscriptable
```

List Comprehension vs Generator Expressions¹³⁶

¹³⁶<https://code-maven.com/list-comprehension-vs-generator-expression>

List comprehension vs Generator Expression - lazy evaluation

The second big difference between list comprehension and generator expressions is that the latter has lazy evaluation.

In this example you can see that once we assign to list comprehension to a variable the `sqr` function is called on each element.

In the case of the generator expression, only when we iterate over the elements will Python call the `sqr` function.

If we exit from the loop before we go over all the values than we saved time by not executing the expression on every element up-front. If the computation is complex and if our list is long, this can have a substantial impact.

```
1 def sqr(n):
2     print(f"sqr {n}")
3     return n ** 2
4
5 numbers = [1, 3, 7]
6
7 # list comprehension
8 n1 = [sqr(n) for n in numbers]
9 print("we have the list")
10 for i in n1:
11     print(i)
12 print("-----")
13
14 # generator expression
15 n2 = (sqr(n) for n in numbers)
16 print("we have the generator")
17 for i in n2:
18     print(i)
```

```
1  sqr 1
2  sqr 3
3  sqr 7
4  we have the list
5  1
6  9
7  49
8  -----
9  we have the generator
10 sqr 1
11 1
12 sqr 3
13 9
14 sqr 7
15 49
```

Generator: function with yield - call next

We can create a function that has multiple `yield` expressions inside.

We call the function and what we get back is a generator.

A generator is also an iterator so we can call the `next` function on it and it will give us the next `yield` value.

If we call it one too many times we get a `StopIteration` exception.

```
1  def number():
2      yield 42
3      yield 19
4      yield 23
5
6  num = number()
7  print(type(num))
8  print(next(num))
9  print(next(num))
10 print(next(num))
11 print(next(num))
```

```
1 <class 'generator'>
2 42
3 19
4 23
5 Traceback (most recent call last):
6   File "simple_generator_next.py", line 11, in <module>
7     print(next(num))
8 StopIteration
```

Generators - call next

We can also use a for loop on the generator and then we don't need to worry about the exception.

```
1 def number():
2     yield 42
3     yield 19
4     yield 23
5
6 num = number()
7 print(type(num))
8 for n in num:
9     print(n)
```

```
1 <class 'generator'>
2 42
3 19
4 23
```

Generator with yield

We don't even need to use a temporary variable for it.

```
1 def number():
2     yield 42
3     yield 19
4     yield 23
5
6 for n in number():
7     print(n)
```

```
1 42
2 19
3 23
```

Generators - fixed counter

```
1 def counter():
2     n = 1
3     yield n
4
5     n += 1
6     yield n
7
8     n += 1
9     yield n
10
11 for c in counter():
12     print(c)
```

```
1 1
2 2
3 3
```

Generators - counter

```
1 def counter():
2     n = 1
3     while True:
4         yield n
5         n += 1
6
7 for c in counter():
8     print(c)
9     if c >= 10:
10        break
```

```
1 1
2 2
3 3
4 4
5 5
6 6
7 7
8 8
9 9
10 10
```

Generators - counter with parameter

```
1 def counter(n = 1):
2     while True:
3         yield n
4         n += 1
5
6 for c in counter():
7     print(c)
8     if c >= 4:
9         break
10 print()
11
12 for c in counter(8):
13     print(c)
14     if c >= 12:
15         break
```

```
1 1
2 2
3 3
4 4
5
6 8
7 9
8 10
9 11
10 12
```

Generators - my_range

```
1 import sys
2
3 def my_range(limit = 1):
4     n = 0
5     while n < limit:
6         yield n
7         n += 1
8
9 for i in my_range(5):
10     print(i)
11 print()
12
13 print(sum(my_range(10)))
14 print()
15
16 x = my_range(10000)
17 print(x)
18 print(sys.getsizeof(x))
```

```
1 0
2 1
3 2
4 3
5 4
6
7 45
8
9 <generator object my_range at 0x7f36f6089930>
10 120
```

Fibonacci - generator

```
1 def fibonacci():
2     a, b = 0, 1
3     while True:
4         a, b = b, a+b
5         yield a
6
7 for a in fibonacci():
8     print(a)
9     if a % 17 == 0:
10        print('found')
11        break
12
13 if a > 200:
14     print('not found')
15     break
```

The fibonacci() function is called 5 times. When it reached the 'yield' command it returns the value as if it was a normal return call, but when the function is called again, it will be executed starting from the next statement. Hence the word 'after' will be printed after each call.

Infinite series

- The Fibonacci was already infinite, let's see a few more.

Integers

```
1 from series import integers
2
3 for i in integers():
4     print(i)
5     if i >= 10:
6         break
```

```
1 1
2 2
3 3
4 4
5 5
6 6
7 7
8 8
9 9
10 10
```

Integers + 3

```
1 from series import integers
2
3 n3 = (n+3 for n in integers())
4 # n3 = integers(3)
5 for i in n3:
6     print(i)
7     if i >= 10:
8         break
```

```
1 4
2 5
3 6
4 7
5 8
6 9
7 10
```

Integers + Integers

```
1  from series import integers
2
3  def mysum(nums):
4      print(nums)
5      total = 0
6      for n in nums:
7          total += n
8      return total
9
10 n3 = integers(3)
11 n7 = integers(7)
12 d = ( mysum(p) for p in zip(n3, n7) )
13
14 print("start")
15 for i in d:
16     print(i)
17     if i >= 20:
18         break
```

```
1  start
2  (3, 7)
3  10
4  (4, 8)
5  12
6  (5, 9)
7  14
8  (6, 10)
9  16
10 (7, 11)
11 18
12 (8, 12)
13 20
```

Filtered Fibonacci

```
1  from series import fibonacci
2
3  even = ( fib for fib in fibonacci() if fib % 2 == 0 )
4  for e in even:
5      print(e)
6      if e > 40:
7          break
```

```
1  0
2  2
3  8
4  34
5  144
```

The series.py

This is the module behind the previous examples.

```
1  def integers(n = 1):
2      while True:
3          yield n
4          n += 1
5
6  def fibonacci():
7      a, b = 0, 1
8      while True:
9          yield a
10         a, b = b, a+b
11
12
13 def gfibonacci(size = 2):
14     """Generalized Fibonacci. """
15     values = [0]
16     while True:
17         yield values[-1]
18         if len(values) < size:
19             values.append(1)
20         else:
21             values.append(sum(values))
22             values = values[1:]
23
```

```
24 def pascal():
25     values = [1]
26     while True:
27         yield values
28         new = [1]
29         for i in range(0, len(values)-1):
30             new.append(values[i] + values[i+1])
31         new.append(1)
32         values = new
```

generator - unbound count (with yield)

```
1 def count(start=0, step=1):
2     n = start
3     while True:
4         yield n
5         n += step
6
7
8 for c in count(start=19, step=1):
9     print(c)
10    if c > 23:
11        break
```

```
1 19
2 20
3 21
4 22
5 23
6 24
```

iterator - cycle

```
1 def cycle(values=[]):
2     my_values = []
3     for v in values:
4         my_values.append(v)
5         yield v
6     while True:
7         for v in my_values:
8             yield v
9
10 i = 0
11 for c in cycle(['A', 'B', 'C']):
12     print(c)
13     i += 1
14     if i >= 4:
15         break
```

```
1 A
2 B
3 C
4 A
```

Exercise: Alternator

Create a generator for the following number series: 1, -2, 3, -4, 5, -6, ...

Exercise: Prime number generator

Create a generator that will return the prime numbers:

2, 3, 5, 7, 11, 13, 17, ...

Exercise: generator

Take the two generator examples (increment number and Fibonacci) and change them to provide infinite iterations.

Then try to run them in a for loop. Just make sure you have some other condition to leave the for-loop.

Exercise: Tower of Hanoi

There are 3 sticks. On the first stick there are n rings of different sizes. The smaller the ring the higher it is on the stick.

Move over all the rings to the 3rd stick by always moving only one ring and making sure that never will there be a large ring on top of a smaller ring.

- [Tower of Hanoi](#)¹³⁷

Exercise: Binary file reader

Create a generator that given a filename and a number n will return the content of the file in chunks of n characters.

Exercise: File reader with records

In a file we have “records” of data. Each record starts with three bytes in which we have the length of the record.

Then the content.

```
1 8 ABCDEFGH 5 XYZQR
```

Given this source file

```
1 First line
2 Second record
3 Third row of the records
4 Fourth
5 5
6 END
```

using this code

¹³⁷https://en.wikipedia.org/wiki/Tower_of_Hanoi

```
1 filename = "rows.txt"
2 records  = "records.txt"
3
4 with open(filename) as in_fh:
5     with open(records, 'w') as out_fh:
6         for line in in_fh:
7             line = line.rstrip("\n")
8             out_fh.write("{:>3}{}".format(len(line), line))
```

we can create this file:

```
1 10First line 13Second record 24Third row of the records 6Fourth 15 3END
```

The exercise is to create an iterator/generator that can read such a file record-by-record.

Logging

Simple logging

```
1 import logging
2
3 logging.debug("debug")
4 logging.info("info")
5 logging.warning("warning")
6 logging.error("error")
7 logging.critical("critical")
8
9 logging.log(logging.WARNING, "another warning")
10 logging.log(40, "another error")
```

```
1 WARNING:root:warning
2 ERROR:root:error
3 CRITICAL:root:critical
4 WARNING:root:another warning
5 ERROR:root:another error
```

- Written on STDERR

Simple logging - set level

```
1 import logging
2
3 logging.basicConfig(level = logging.INFO)
4
5 logging.debug("debug")
6 logging.info("info")
7 logging.warning("warning")
8 logging.error("error")
9 logging.critical("critical")
```

```
1 INFO:root:info
2 WARNING:root:warning
3 ERROR:root:error
4 CRITICAL:root:critical
```

Simple logging to a file

```
1 import logging
2 import time
3
4 logging.basicConfig(level = logging.INFO, filename = time.strftime("my-%Y-%m-%d.log"\
5 ))
6
7 logging.debug("debug")
8 logging.info("info")
9 logging.warning("warning")
10 logging.error("error")
11 logging.critical("critical")
```

Simple logging format

```
1 import logging
2
3 logging.basicConfig( format = '%(asctime)s %(levelname)-10s %(processName)s %(name\
4 )s %(message)s')
5
6 logging.debug("debug")
7 logging.info("info")
8 logging.warning("warning")
9 logging.error("error")
10 logging.critical("critical")
```

Simple logging change date format

```

1  import logging
2
3  logging.basicConfig( format = '%(asctime)s %(levelname)-10s %(processName)s %(name\
4  )s %(message)s', datefmt = "%Y-%m-%d-%H-%M-%S")
5
6  logging.debug("debug")
7  logging.info("info")
8  logging.warning("warning")
9  logging.error("error")
10 logging.critical("critical")

```

```

1  2020-04-22-18-59-16  WARNING      MainProcess  root warning
2  2020-04-22-18-59-16  ERROR       MainProcess  root error
3  2020-04-22-18-59-16  CRITICAL    MainProcess  root critical

```

getLogger

```

1  import logging
2
3  logger = logging.getLogger(__name__)
4  logger.setLevel(logging.DEBUG)
5
6  fh = logging.FileHandler('my.log')
7  fh.setLevel(logging.INFO)
8  fh.setFormatter( logging.Formatter('%(asctime)s - %(name)s - %(levelname)-10s - %(me\
9  ssage)s') )
10 logger.addHandler(fh)
11
12
13 sh = logging.StreamHandler()
14 sh.setLevel(logging.DEBUG)
15 sh.setFormatter(logging.Formatter('%(asctime)s - %(levelname)-10s - %(message)s'))
16 logger.addHandler(sh)
17
18
19
20 log = logging.getLogger(__name__)
21 log.debug("debug")
22 log.info("info")
23 log.warning("warning")
24 log.error("error")
25 log.critical("critical")

```

Time-based logrotation

```
1 import logging
2
3 log_file = "my.log"
4
5 logger = logging.getLogger(__name__)
6 logger.setLevel(logging.DEBUG)
7
8 ch = logging.handlers.TimedRotatingFileHandler(log_file, when='M', backupCount=2)
9 ch.setLevel(logging.INFO)
10 ch.setFormatter( logging.Formatter('%(asctime)s - %(name)s - %(levelname)-10s - %(message)s') )
11
12 logger.addHandler(ch)
13
14
15 log = logging.getLogger(__name__)
16 log.debug("debug")
17 log.info("info")
18 log.warning("warning")
19 log.error("error")
20 log.critical("critical")
```

Size-based logrotation

```
1 import logging
2
3 log_file = "my.log"
4
5 logger = logging.getLogger(__name__)
6 logger.setLevel(logging.DEBUG)
7
8 ch = logging.handlers.RotatingFileHandler(log_file, maxBytes=100, backupCount=2)
9 ch.setLevel(logging.INFO)
10 ch.setFormatter( logging.Formatter('%(asctime)s - %(name)s - %(levelname)-10s - %(message)s') )
11
12 logger.addHandler(ch)
13
14
15 log = logging.getLogger(__name__)
16 log.debug("debug")
```

```
17 log.info("info")
18 log.warning("warning")
19 log.error("error")
20 log.critical("critical")
```

Closures

Counter local - not working

```
1 def counter():
2     count = 0
3     count += 1
4     return count
5
6 print(counter())
7 print(counter())
8 print(counter())
```

```
1 1
2 1
3 1
```

Counter with global

```
1 count = 0
2 def counter():
3     global count
4     count += 1
5     return count
6
7 print(counter())
8 print(counter())
9 print(counter())
10
11 count = -42
12 print(counter())
```

```
1 1
2 2
3 3
4 -41
```

Create incrementors

In order to use in various map-expressions, we need a couple of functions that - for simplicity - need to increment a number:

```
1 def f3(x):
2     return x + 3
3
4 def f7(x):
5     return x + 7
6
7 def f23(x):
8     return x + 23
9
10 print(f3(2))
11 print(f7(3))
12 print(f3(4))
13 print(f7(10))
14 print(f23(19))
```

```
1 5
2 10
3 7
4 17
5 42
```

Create internal function

```
1 def create_func():
2     def internal():
3         print("Hello world")
4     internal()
5
6
7 func = create_func()
8 internal()

1 Hello world
2 Traceback (most recent call last):
3   File "create_internal_func.py", line 8, in <module>
4     internal()
5 NameError: name 'internal' is not defined
```

Create function by a function

```
1 def create_func():
2     def internal():
3         print("Hello world")
4     #internal()
5
6     return internal
7
8 func = create_func()
9 #internal()
10 func()
```

```
1 Hello world
```

Create function with parameters

```
1 def create_func(name):
2     def internal():
3         print(f"Hello {name}")
4
5     return internal
6
7 foo = create_func("Foo")
8 foo()
9
10
11 bar = create_func("Bar")
12 bar()

1 Hello Foo
2 Hello Bar
```

Counter closure

```
1 def create_counter():
2     count = 0
3     def internal():
4         nonlocal count
5         count += 1
6         return count
7     return internal
8
9 counter = create_counter()
10
11 print(counter())
12 print(counter())
13 print(counter())
14 print()
15
16 other = create_counter()
17 print(counter())
18 print(other())
19 print(counter())
20 print(other())
21
22 print()
23 print(count)
```

```
1  1
2  2
3  3
4
5  4
6  1
7  5
8  2
9
10 Traceback (most recent call last):
11   File "counter.py", line 23, in <module>
12     print(count)
13 NameError: name 'count' is not defined
```

Make incrementor with def (closure)

```
1  def make_incrementor(n):
2      def inc(x):
3          return x + n
4      return inc
5
6  f3 = make_incrementor(3)
7  f7 = make_incrementor(7)
8
9  print(f3(2))
10 print(f7(3))
11 print(f3(4))
12 print(f7(10))
```

```
1  5
2  10
3  7
4  17
```

Make incrementor with lambda

```
1 def make_incrementor(n):
2     return lambda x: x + n
3
4 f3 = make_incrementor(3)
5 f7 = make_incrementor(7)
6
7 print(f3(2))
8 print(f7(3))
9 print(f3(4))
10 print(f7(10))
```

```
1 5
2 10
3 7
4 17
```

Exercise: closure bank

- Create a closure that returns a function that holds a number (like a bank account) that can be incremented or decremented as follows:
- Allow for an extra parameter called `prev` that defaults to `False`. If `True` is passed then instead of returning the new balance, return the old balance.

```
1 bank = create_bank(20)
2
3 print(bank())    # 20
4 print(bank(7))   # 27
5 print(bank())    # 27
6 print(bank(-3))  # 24
7 print(bank())    # 24
8
9
10 print(bank(10, prev=True))  # 24
11 print(bank())              # 34
```

Exercise: counter with parameter

Change the counter example to accept a parameter and start counting from that number.

Solution: closure bank

```
1 def create_bank(n = 0):
2     balance = n
3     def bnk(change = 0, prev=False):
4         nonlocal balance
5         prev_balance = balance
6         balance += change
7         if prev:
8             return prev_balance
9         else:
10            return balance
11    return bnk
12
13
14 bank = create_bank(20)
15
16 print(bank())    # 20
17 print(bank(7))   # 27
18 print(bank())    # 27
19 print(bank(-3))  # 24
20 print(bank())    # 24
21
22
23 print(bank(10, prev=True))    # 24
24 print(bank())    # 34
```

```
1 20
2 27
3 27
4 24
5 24
6 24
7 34
```

Solution: counter with parameter

```
1 def create_counter(count=0):
2     def internal():
3         nonlocal count
4         count += 1
5         return count
6     return internal
7
8 counter = create_counter()
9
10 print(counter())
11 print(counter())
12 print(counter())
13 print()
14
15 other = create_counter(42)
16 print(counter())
17 print(other())
18 print(counter())
19 print(other())
```

```
1 1
2 2
3 3
4
5 4
6 43
7 5
8 44
```

Decorators

Function assignment

Before we learn about decorators let's remember that we can assign function names to other names and then use the new name:

```
1 say = print
2 say("Hello World")
3
4 print = lambda n: n**n
5 res = print(3)
6 say("Hi")
7 say(res)
8
9
10 def add(x, y):
11     return x + y
12
13 combine = add
14
15 say( combine(2, 3) )
```

```
1 Hello World
2 Hi
3 27
4 5
```

Function inside other function

Let's also remember that we can define a function inside another function and then the internally defined function only exists in the scope of the function

where it was defined in. Not outside.

```
1 def f():
2     def g():
3         print("in g")
4     print("start f")
5     g()
6     print("end f")
7
8 f()
9 g()
```

```
1 start f
2 in g
3 end f
4 Traceback (most recent call last):
5   File "examples/decorators/function_in_function.py", line 9, in <module>
6     g()
7 NameError: name 'g' is not defined
```

Decorator

- A function that changes the behaviour of other functions.
- The input of a decorator is a function.
- The returned value of a decorator is a modified version of the same function.

```
1 from some_module import some_decorator
2
3 @some_decorator
4 def f(...):
5     ...
```

```
1 def f(...):
2     ...
```

```
1 f = some_decorator(f)
```

Use cases for decorators in Python

- Common decorators are `classmethod()` and `staticmethod()`.
- Flask uses them to mark and configure the routes.
- Pytest uses them to add marks to the tests.

- Logging calls with parameters.
- Logging elapsed time of calls.
- Access control in Django or other web frameworks. (e.g. login required)
- Memoization (caching)
- Retry
- Function timeout
- Locking for thread safety
- [Decorator Library](#)¹³⁸

A recursive Fibonacci

```
1 def fibo(n):  
2     if n in (1,2):  
3         return 1  
4     return fibo(n-1) + fibo(n-2)  
5  
6 print(fibo(5)) # 5
```

trace fibo

¹³⁸<https://wiki.python.org/moin/PythonDecoratorLibrary>

```
1  import decor
2
3  @decor.tron
4  def fibo(n):
5      if n in (1,2):
6          return 1
7      return fibo(n-1) + fibo(n-2)
8
9  print(fibo(5))
```

```
1  Calling fibo(5)
2  Calling fibo(4)
3  Calling fibo(3)
4  Calling fibo(2)
5  Calling fibo(1)
6  Calling fibo(2)
7  Calling fibo(3)
8  Calling fibo(2)
9  Calling fibo(1)
10 5
```

tron decorator

```
1  def tron(func):
2      def new_func(v):
3          print("Calling {}({})".format(func.__name__, v))
4          return func(v)
5      return new_func
```

Decorate with direct call

```
1  import decor
2
3  def fibo(n):
4      if n in (1,2):
5          return 1
6      return fibo(n-1) + fibo(n-2)
7
8  fibo = decor.tron(fibo)
9
10 print(fibo(5))
```

Decorate with parameter

```
1  import decor_param
2
3  @decor_param.tron('foo')
4  def fibo(n):
5      if n in (1,2):
6          return 1
7      return fibo(n-1) + fibo(n-2)
8
9  print(fibo(5))
```

```
1  foo Calling fibo(5)
2  foo Calling fibo(4)
3  foo Calling fibo(3)
4  foo Calling fibo(2)
5  foo Calling fibo(1)
6  foo Calling fibo(2)
7  foo Calling fibo(3)
8  foo Calling fibo(2)
9  foo Calling fibo(1)
10 5
```

Decorator accepting parameter

```
1 def tron(prefix):
2     def real_tron(func):
3         def new_func(v):
4             print("{} Calling {}({})".format(prefix, func.__name__, v))
5             return func(v)
6         return new_func
7     return real_tron
```

Decorate function with any signature

- How can we decorate a function that is flexible on the number of arguments?
- Accept `*args` and `**kwargs` and pass them on.

```
1 from decor_any import tron
2
3
4 @tron
5 def one(param):
6     print(f"one({param})")
7
8 @tron
9 def two(first, second = 42):
10    print(f"two({first}, {second})")
11
12
13 one("hello")
14 one(param = "world")
15
16 two("hi")
17 two(first = "Foo", second = "Bar")
```

Decorate function with any signature - implementation

```
1 def tron(func):
2     def new_func(*args, **kw):
3         params = list(map(lambda p: str(p), args))
4         for (k, v) in kw.items():
5             params.append(f"{k}={v}")
6         print("Calling {}".format(func.__name__, ' '.join(params)))
7         return func(*args, **kw)
8     return new_func

1 Calling one(hello)
2 one(hello)
3 Calling one(param=world)
4 one(world)
5 Calling two(hi)
6 two(hi, 42)
7 Calling two(first=Foo, second=Bar)
8 two(Foo, Bar)
```

Exercise: Logger decorator

- In the previous pages we created a decorator that can decorate arbitrary function logging the call and its parameters.
- Add time measurement to each call to see how long each function took.

Exercise: memoize decorator

Write a function that gets a functions as attribute and returns a new functions while memoizing (caching) the input/output pairs.

Then write a unit test that checks it.

You probably will need to create a subroutine to be memoized.

- Write tests for the fibonacci functions.
- Implement the memoize decorator for a function with a single parameter.
- Apply the decorator.
- Run the tests again.
- Check the speed differences.
- or decorate with tron to see the calls...

Solution: Logger decorator

```

1  import time
2  def tron(func):
3      def new_func(*args, **kwargs):
4          start = time.time()
5          print("Calling {}({}, {})".format(func.__name__, args, kwargs))
6          out = func(*args, **kwargs)
7          end = time.time()
8          print("Finished {}({})".format(func.__name__, out))
9          print("Elapsed time: {}".format(end - start))
10         return out
11     return new_func

```

Solution: Logger decorator (testing)

```

1  from logger_decor import tron
2
3  @tron
4  def f(a, b=1, *args, **kwargs):
5      print('a:      ', a)
6      print('b:      ', b)
7      print('args:   ', args)
8      print('kwargs: ', kwargs)
9      return a + b
10

6 sys     0m0.014s
```

Context managers (with statement)

Why use context managers?

In certain operations you might want to ensure that when the operation is done there will be an opportunity to clean up after it. Even if decided to end the operation early or if there is an exception in the middle of the operation.

In the following pseudo-code example you can see that `cleanup` must be called both at the end and before the `early-end`, but that still leaves the bad-code that raises exception avoiding the cleanup. That forces us to wrap the whole section in a try-block.

```
1 start
2 do
3 do
4 do
5 do
6 cleanup
```

What if we have some conditions for early termination?

```
1 start
2 do
3 do
4 if we are done early:
5     cleanup
6     early-end
7 do
8 do
9 cleanup
```

What if we might have an exception in the code?

```
1 start
2 try:
3     do
4     do
5     if we are done early:
6         cleanup
7         early-end
8     do
9     bad-code    (raises exception)
10    do
11    cleanup
12 finally:
13    cleanup
```

It is a lot of unnecessary code duplication and we can easily forget to add it in every location where we early-end our code.

Context Manager examples

A few examples where context managers can be useful:

- Opening a file - close it once we are done with it so we don't leak file descriptors.
- Changing directory - change back when we are done.
- Create temporary directory - remove when we are done.
- Open connection to database - close connection.
- Open SSH connection - close connection.
- More information about [context managers](https://jeffknupp.com/blog/2016/03/07/python-with-context-managers/)¹³⁹

cd in a function

In this example we have a function in which we change to a directory and then when we are done we change back to the original directory.

For this to work first we save the current working directory using the `os.getcwd` call. Unfortunately in the middle of the code there

is a conditional call to `return`. If that condition is `True` we won't change back to the original directory.

We could fix this by

calling `os.chdir(start_dir)` just before calling `return`. However this would still not solve the

¹³⁹<https://jeffknupp.com/blog/2016/03/07/python-with-context-managers/>

problem if there is an exception
in the function.

```
1  import sys
2  import os
3
4  def do_something(path):
5      start_dir = os.getcwd()
6      os.chdir(path)
7
8      content = os.listdir()
9      number = len(content)
10     print(number)
11     if number < 15:
12         return
13
14     os.chdir(start_dir)
15
16 def main():
17     if len(sys.argv) != 2:
18         exit(f"Usage: {sys.argv[0]} PATH")
19     path = sys.argv[1]
20     print(os.getcwd())
21     do_something(path)
22     print(os.getcwd())
23
24 main()
```

```
1  $ python no_context_cd.py /tmp/
2
3  /home/gabor/work/slides/python-programming/examples/advanced
4  19
5  /home/gabor/work/slides/python-programming/examples/advanced
```

```
1 $ python no_context_cd.py /opt/  
2  
3 /home/gabor/work/slides/python-programming/examples/advanced  
4 9  
5 /opt
```

- In the second example `return` was called and thus we stayed on the `/opt` directory.:w

open in function

This is not the recommended way to open a file, but this is how it was done before the introduction of the `with` context manager.

Here we have the same issue. We have a conditional call to `return` where we forgot to close the file.

```
1 import sys  
2 import re  
3  
4 def do_something(filename):  
5     fh = open(filename)  
6  
7     while True:  
8         line = fh.readline()  
9         if line is None:  
10             break  
11         line = line.rstrip("\n")  
12  
13         if re.search(r'\A\s*\Z', line):  
14             return  
15         print(line)  
16  
17     fh.close()  
18  
19 def main():  
20     if len(sys.argv) != 2:  
21         exit(f"Usage: {sys.argv[0]} FILENAME")  
22     filename = sys.argv[1]  
23     do_something(filename)  
24  
25 main()
```

open in for loop

Calling `write` does not immediately write to disk. The Operating System provides buffering as an optimization to avoid frequent access to the disk. In this case it means the file has not been saved before we already check its size.

```
1  import os
2
3  for ix in range(10):
4      filename = f'data{ix}.txt'
5      fh = open(filename, 'w')
6      fh.write('hello')
7      if ix == 0:
8          break
9      fh.close()
10 stat = os.stat(filename)
11 print(stat.st_size)    # 0,    the file has not been saved yet
```

open in function using with

If we open the file in the recommended way using the `with` statement then we can be sure that the `close` method of the `fh` object will be called when we leave the context of the `with` statement.

```
1  import sys
2  import re
3
4  def do_something(filename):
5      with open(filename) as fh:
6
7          while True:
8              line = fh.readline()
9              if line is None:
10                 break
11                 line = line.rstrip("\n")
```

```

12
13         if re.search(r'\A\s*\Z', line):
14             return
15         print(line)
16
17
18 def main():
19     if len(sys.argv) != 2:
20         exit(f"Usage: {sys.argv[0]} FILENAME")
21     filename = sys.argv[1]
22     do_something(filename)
23
24 main()

```

Plain context manager

```

1  from contextlib import contextmanager
2
3  @contextmanager
4  def my_plain_context():
5      print("start context")
6      yield
7      print("end context")
8
9  print("START")
10 with my_plain_context():
11     print("  In plain context")
12     print("  More work")
13
14 print("END")

```

```

1  START
2  start context
3    In plain context
4    More work
5  end context
6  END

```

Param context manager

```
1  from contextlib import contextmanager
2
3  @contextmanager
4  def my_param_context(name):
5      print(f"start {name}")
6      yield
7      print(f"end {name}")
8
9  with my_param_context("foo"):
10     print("In param context")
```

```
1  start foo
2  In param context
3  end foo
```

Context manager that returns a value

```
1  from contextlib import contextmanager
2
3  import time
4  import random
5  import os
6  import shutil
7
8
9  @contextmanager
10 def my_tmpdir():
11     print("start return")
12     tmpdir = '/tmp/' + str(time.time()) + str(random.random())
13     os.mkdir(tmpdir)
14     try:
15         yield tmpdir
16     finally:
17         shutil.rmtree(tmpdir)
18     print("end return")
```

```

1  import os
2  from my_tempdir import my_tempdir
3
4  with my_tempdir() as tmp_dir:
5      print(f"In return context with {tmp_dir}")
6      with open(tmp_dir + '/data.txt', 'w') as fh:
7          fh.write("hello")
8      print(os.listdir(tmp_dir))
9
10 print('')
11 print(tmp_dir)
12 print(os.path.exists(tmp_dir))

```

```

1  start return
2  In return context with /tmp/1578211890.49409370.6063140788762365
3  ['data.txt']
4  end return
5
6  /tmp/1578211890.49409370.6063140788762365
7  False

```

Use my tempdir - return

```

1  import os
2  from my_tempdir import my_tempdir
3
4  def some_code():
5      with my_tempdir() as tmp_dir:
6          print(f"In return context with {tmp_dir}")
7          with open(tmp_dir + '/data.txt', 'w') as fh:
8              fh.write("hello")
9          print(os.listdir(tmp_dir))
10         return
11
12     print('')
13     print(tmp_dir)
14     print(os.path.exists(tmp_dir))
15
16 some_code()

```

```

1 start return

18         cm.something()
19         #raise Exception('nono')
20     print('in main - after')
21
22 main()
23 print('after main')
```

Context managers with class

Even if there was an exception in the middle of the process, the exit methods of each object will be called.

```
1 class MyCM:
2     def __init__(self, n):
3         self.name = n
4
5     def __enter__(self):
6         print('__enter__', self.name)
7
8     def __exit__(self, exception_type, exception, traceback):
9         print('__exit__', self.name)
10
11    def something(self):
12        print('something', self.name)
13
```

```

14 def main():
15     a = MyCM('a')
16     b = MyCM('b')
17     with a, b:
18         a.partner = b
19         b.partner = a
20         a.something()
21         raise Exception('nono')
22         b.something()
23     print('in main - after')
24
25 main()
26 print('after main')

```

```

1  __enter__ a
2  __enter__ b
3  something a
4  __exit__ b
5  __exit__ a
6  Traceback (most recent call last):
7    File "context-managers.py", line 27, in <module>
8      main()
9    File "context-managers.py", line 23, in main
10      raise Exception('nono')
11  Exception: nono

```

Context manager: with for file

```

1  import sys
2
3  if len(sys.argv) != 2:
4      sys.stderr.write('Usage: {} FILENAME\n'.format(sys.argv[0]))
5      exit()
6
7  file = sys.argv[1]
8  print(file)
9  with open(file) as f:
10     for line in f:
11         val = 30/int(line)
12
13  print('done')

```

With - context managers

```
1 class WithClass:
2     def __init__(self, name='default'):
3         self.name = name
4
5     def __enter__(self):
6         print('entering the system')
7         return self.name
8
9     def __exit__(self, exc_type, exc_value, traceback):
10        print('exiting the system')
11
12    def __str__(self):
13        return 'WithObject:'+self.name
14
15 x = WithClass()
16 with x as y:
17     print(x,y)
```

Exercise: Context manager

Create a few CSV file likes these:

```
1 a11,a12
2 a21,a22
```

```
1 b13,b14
2 b23,b24
```

```
1 c15,c16
2 c25,c26
```

Merge them horizontally to get this:

```
1 a11,a12,b13,b14,c15,c16
2 a21,a22,b23,b24,c25,c26
```

- Do it without your own context manager
- Create a context manager called myopen that accepts N filenames. It opens the first one to write and the other N-1 to read

```
1 with myopen(outfile, infile1, infile2, infile3) as out, ins:
2     ...
```

Exercise: Tempdir on Windows

Make the tempdir context manager example work on windows as well. Probably need to cd out of the directory.

Solution: Context manager

```
1 import sys
2 from contextlib import contextmanager
3
4 if len(sys.argv) < 3:
5     exit(f"Usage: {sys.argv[0]} OUTFILE INFILES")
6
7 outfile = sys.argv[1]
8 infiles = sys.argv[2:]
9 #print(outfile)
10 #print(infiles)
11
12 @contextmanager
13 def myopen(outfile, *infiles):
14     #print(len(infiles))
15     out = open(outfile, 'w')
16     ins = []
17     for filename in infiles:
18         ins.append(open(filename, 'r'))
19     try:
20         yield out, ins
21     except Exception as ex:
22         print(ex)
23         pass
24     finally:
25         out.close()
26         for fh in ins:
27             fh.close()
28
29
30 with myopen(outfile, *infiles) as (out_fh, input_fhs):
31     #print(out_fh.__class__.__name__)
```

```
32     #print(len(input_fhs))
33     while True:
34         row = ''
35         done = False
36         for infh in input_fhs:
37             line = infh.readline()
38             #print(f"{'{line}'}")
39             if not line:
40                 done = True
41                 break
42             if row:
43                 row += ', '
44             row += line.rstrip("\n")
45         if done:
46             break
47         out_fh.write(row)
48         out_fh.write("\n")
```

Advanced lists

Change list while looping: endless list

```
1 numbers = [1, 1]
2 for n in numbers:
3     print(n)
4     numbers.append(numbers[-1] + numbers[-2])
5
6     if n > 100:
7         break
8
9 print(numbers)
```

Creating a Fibonacci series in a crazy way.

Change list while looping

Probably not a good idea...

```
1 numbers = [1, 2, 3, 4]
2 for n in numbers:
3     print(n)
4     if n == 2:
5         numbers.remove(2)
6
7
8 print(numbers)
```

```
1 1
2 2
3 4
4 [1, 3, 4]
```

Note, the loop only iterated 3 times, and it skipped value 3

Copy list before iteration

It is better to copy the list using list slices before the iteration starts.

```
1 numbers = [1, 2, 3, 4]
2 for n in numbers[:]:
3     print(n)
4     if n == 2:
5         numbers.remove(2)
6
7
8 print(numbers)
```

```
1 1
2 2
3 3
4 4
5 [1, 3, 4]
```

for with flag

```
1 names = ['Foo', 'Bar', 'Baz']
2
3 ok = False
4 for i in range(3):
5     name = input('Your name please: ')
6     if name in names:
7         ok = True
8         break
9
10 if not ok:
11     print("Not OK")
12     exit()
13
14 print("OK....")
```

for else

The else statement of the for loop is executed when the iteration ends normally. (without calling break)

```
1 names = ['Foo', 'Bar', 'Baz']
2
3
4 for i in range(3):
5     name = input('Your name please: ')
6     if name in names:
7         break
8 else:
9     print("Not OK")
10    exit()
11
12 print("OK....")
```

enumerate

```
1 names = ['Foo', 'Bar', 'Baz']
2
3 for i in range(len(names)):
4     print(i, names[i])
5
6 print('')
7
8 for i, n in enumerate(names):
9     print(i, n)
```

```
1 0 Foo
2 1 Bar
3 2 Baz
4
5 0 Foo
6 1 Bar
7 2 Baz
```

do while

There is no do-while in Python, but you can emulate it:

```
1 while True:
2     do_stuff()
3     if not loop_condition():
4         break
```

```
1 x = 0
2
3 while True:
4     x += 1
5     print(x)
6     if x > 0:
7         break
```

list slice is copy

```
1 x = [1, 1, 2, 3, 5, 8, 13, 21, 34]
2 y = x[2:5]
3 print(y)    # [2, 3, 5]
4
5 x[2] = 20
6 print(x)    # [1, 1, 20, 3, 5, 8, 13, 21, 34]
7 print(y)    # [2, 3, 5]
```

Advanced Exception handling

Exceptions else

- The else part will be execute after each successful “try”. (So when there was no exception.)

```
1  import sys
2  import module
3
4  # python else.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except ZeroDivisionError as err:
11         print("Exception {} of type {} in file {}".format(err, type(err).__name__, f\
12 ilename))
13     else:
14         print("In else part after trying file {} and succeeding".format(filename))
15         # Will run only if there was no exception.
16     print()
```

```
1  before one.txt
2  100.0
3  after one.txt
4  In else part after trying file one.txt and succeeding
5
6  before zero.txt
7  Exception division by zero of type ZeroDivisionError in file zero.txt
8
9  before two.txt
10 Traceback (most recent call last):
11   File "else.py", line 9, in <module>
12     module.read_and_divide(filename)
13   File "/home/gabor/work/slides/python-programming/examples/exceptions/module.py", 1\
14 ine 3, in read_and_divide
15     with open(filename, 'r') as fh:
16 FileNotFoundError: [Errno 2] No such file or directory: 'two.txt'
```

Exceptions finally

- We can add a “finally” section to the end of the “try” - “except” construct.
- The code in this block will be executed after **every** time we enter the **try**.
- When we finish it successfully. When we catch an exception. (In this case a ZeroDivisionError exception in file zero.txt)
- Even when we don’t catch an exception. Before the exception propagates up in the call stack, we still see the “finally” section executed.

```

1  import sys
2  import module
3
4  # python finally.py one.txt zero.txt two.txt three.txt
5  files = sys.argv[1:]
6
7  for filename in files:
8      try:
9          module.read_and_divide(filename)
10     except ZeroDivisionError as err:
11         print("Exception {} of type {} in file {}".format(err, type(err).__name__, f\
12 ilename))
13     finally:
14         print("In finally after trying file {}".format(filename))
15     print('')
```

```

1  before one.txt
2  100.0
3  after one.txt
4  In finally after trying file one.txt
5
6  before zero.txt
7  Exception division by zero of type ZeroDivisionError in file zero.txt
8  In finally after trying file zero.txt
9
10 before two.txt
11 In finally after trying file two.txt
12 Traceback (most recent call last):
13   File "finally.py", line 9, in <module>
14     module.read_and_divide(filename)
15   File "/home/gabor/work/slides/python-programming/examples/exceptions/module.py", 1\
```

```
16  ine 3, in read_and_divide
17      with open(filename, 'r') as fh:
18  FileNotFoundError: [Errno 2] No such file or directory: 'two.txt'
```

Exit and finally

The “finally” part will be called even if we call “return” or “exit” in the “try” block.

```
1  def f():
2      try:
3          return
4      finally:
5          print("finally in f")
6
7  def g():
8      try:
9          exit()
10     finally:
11         print("finally in g")
12
13  print("before")
14  f()
15  print("after f")
16  g()
17  print("after g")
18
19  # before
20  # finally in f
21  # after f
22  # finally in g
```

Catching exceptions

```

1  def divide(x, y):
2      return x/y
3
4  def main():
5      cnt = 6
6      for num in [2, 0, 'a']:
7          try:
8              divide(cnt, num)
9          except ZeroDivisionError:
10             pass
11          except (IOError, MemoryError) as err:
12             print(err)
13          else:
14             print("This will run if there was no exception at all")
15          finally:
16             print("Always executes. {}/{} ended.".format(cnt, num))
17
18      print("done")
19
20
21  main()

```

```

1  This will run if there was no exception at all
2  Always executes. 6/2 ended.
3  Always executes. 6/0 ended.
4  Always executes. 6/a ended.
5  Traceback (most recent call last):
6    File "try.py", line 22, in <module>
7      main()
8    File "try.py", line 9, in main
9      divide(cnt, num)
10   File "try.py", line 3, in divide
11     return x/y
12 TypeError: unsupported operand type(s) for /: 'int' and 'str'

```

Home made exception

You can create your own exception classes that will allow the user to know what kind of an exception

was caught or to capture only the exceptions of that type.

```
1 class MyException(Exception):
2     pass
3
4 def some():
5     raise MyException("Some Error")
6
7 def main():
8     try:
9         some()
10    except Exception as err:
11        print(err)
12        print("Type: " + type(err).__name__)
13
14    try:
15        some()
16    except MyException as err:
17        print(err)
18
19 main()
```

```
1 Some Error
2 Type: MyException
3 Some Error
```

Home made exception with attributes

```
1 class MyException(Exception):
2     def __init__(self, name, address):
3         self.name = name
4         self.address = address
5     def __str__(self):
6         return 'Have you encountered problems? name:{} address:{}'.format(self.name\
7 , self.address)
8
9
10 def some():
```

```
11     raise MyException(name = "Foo Bar", address = "Somewhere deep in the code")
12
13 def main():
14     try:
15         some()
16     except Exception as err:
17         print(err)
18         print("Type: " + type(err).__name__)
19         print(err.name)
20         print(err.address)
21
22 main()
23
24 # Have you encountered problems? name:Foo Bar  address:Somewhere deep in the code
25 # Type: MyException
26 # Foo Bar
27 # Somewhere deep in the code
```

Home made exception hierarchy

```
1 class MyError(Exception):
2     pass
3
4 class MyGreenError(MyError):
5     pass
6
7 class MyBlueError(MyError):
8     pass
9
10
11 def green():
12     raise MyGreenError('Hulk')
13
14 def blue():
15     raise MyBlueError('Frozen')
16
17 def red():
18     red_alert()
```

Home made exception hierarchy - 1

```
1  import colors as cl
2
3  def main():
4      print("start")
5      try:
6          cl.green()
7      except Exception as err:
8          print(err)
9          print(type(err).__name__)
10     print("done")
11
12
13 main()
```

```
1  start
2  Hulk
3  MyGreenError
4  done
```

Home made exception hierarchy - 2

```
1  import colors as cl
2
3  def main():
4      print("start")
5      try:
6          cl.green()
7      except cl.MyGreenError as err:
8          print(err)
9          print(type(err).__name__)
10     print("done")
11
12
13 main()
```

```
1  start
2  Hulk
3  MyGreenError
4  done
```

Home made exception hierarchy - 3

```
1  import colors as cl
2
3  def main():
4      print("start")
5
6      try:
7          cl.green()
8      except cl.MyError as err:
9          print(err)
10         print(type(err).__name__)
11
12     try:
13         cl.blue()
14     except cl.MyError as err:
15         print(err)
16         print(type(err).__name__)
17
18     try:
19         cl.red()
20     except cl.MyError as err:
21         print(err)
22         print(type(err).__name__)
23
24
25
26
27     print("done")
28
29
30 main()
```

```
1  start
2  Hulk
3  MyGreenError
4  Frozen
5  MyBlueError
6  Traceback (most recent call last):

```

```
12 ed
13     red_alert()
14 NameError: name 'red_alert' is not defined
```

Exercise: spacefight with exceptions

Take the number guessing game (or one-dimensional space-fight) and add exceptions for cases when the guess is out of space (0-200 by default), or when the guess is not a number.

```
1  import random
2
3  class Game:
4      def __init__(self):
5          self.lower_limit = 0
6          self.upper_limit = 200
7
8          self.number = random.randrange(self.lower_limit, self.upper_limit)
9          self.is_debug = False
10         self.running = True
11
12     def debug(self):
13         self.is_debug = not self.is_debug
14
15     def guess(self, num):
16         if num == 'd':
17             self.debug()
18             return
19
20         if self.is_debug:
21             print("Hidden number {}. Your guess is {}".format(self.number, num))
22
23         if num < self.number:
24             print("Too small")
25         elif num > self.number:
26             print("Too big")
27         else:
28             print("Bingo")
29             self.running = False
30
31
32 g = Game()
```

```
33 g.guess('d')
34
35 try:
36     g.guess('z')
37 except Exception as e:
38     print(e)
39
40 try:
41     g.guess('201')
42 except Exception as e:
43     print(e)
44
45 try:
46     g.guess('-1')
47 except Exception as e:
48     print(e)
```

Exercies: Raise My Exception

This is very similar to the exercise the first chapter about exceptions, but in this case you need to create your own hierarchy of exception classes.

- Write a function that expects a positive integer as its single parameter.
- Raise exception if the parameter is not a number.
- Raise a different exception if the parameter is not positive.
- Raise a different exception if the parameter is not whole number.
- In each case make sure both the text and the type of the exceptions are different.
- Include the actual value received as an attribute in the exception object.

Solution: spacefight with exceptions

```
1  import random
2
3  class SpaceShipError(Exception):
4      def __init__(self, inp):
5          self.inp = inp
6
7  class NumberTooBigError(SpaceShipError):
8      def __str__(self):
9          return "Number {} is too big".format(self.inp)
10
11 class NumberTooSmallError(SpaceShipError):
12     def __str__(self):
13         return "Number {} is too small".format(self.inp)
14
15
16 class NotANumberError(SpaceShipError):
17     def __str__(self):
18         return "Not a Number {}".format(self.inp)
19
20
21 class Game:
22     def __init__(self):
23         self.lower_limit = 0
24         self.upper_limit = 200
25
26         self.number = random.randrange(self.lower_limit, self.upper_limit)
27         self.is_debug = False
28         self.running = True
29
30     def debug(self):
31         self.is_debug = not self.is_debug
32
33     def guess(self, num):
34         if num == 'd':
35             self.debug()
36             return
37
38         if self.is_debug:
39             print("Hidden number {}. Your guess is {}".format(self.number, num))
40
41         try:
42             num = int(num)
43         except Exception:
```

```
44         raise NotANumberError(num)
45
46     if num > self.upper_limit:
47         raise NumberTooBigError(num)
48
49     if num < self.lower_limit:
50         raise NumberTooSmallError(num)
51
52     if num < self.number:
53         print("Too small")
54     elif num > self.number:
55         print("Too big")
56     else:
57         print("Bingo")
58         self.running = False
59
60
61 g = Game()
62 g.guess('d')
63
64 try:
65     g.guess('z')
66 except Exception as e:
67     print(e)
68
69 try:
70     g.guess('201')
71 except Exception as e:
72     print(e)
73
74 try:
75     g.guess('-1')
76 except Exception as e:
77     print(e)
78
79
80
81 #while g.running:
82 #     guess = input("Please type in your guess: ")
83 #     g.guess(int(guess))
```

```
1 Hidden number 137. Your guess is z
2 Not a Number z
3 Hidden number 137. Your guess is 201
4 Number 201 is too big
5 Hidden number 137. Your guess is -1
6 Number -1 is too small
```

Solution: Raise My Exception

```
1 class MyValueError(ValueError):
2     def __init__(self, val):
3         self.value = val
4
5 class MyFloatError(MyValueError):
6     def __str__(self):
7         return "The given parameter {} is a float and not an int.".format(self.value)
8
9 class MyTypeError(MyValueError):
10    def __init__(self, val, val_type):
11        self.value_type = val_type
12        super(MyTypeError, self).__init__(val)
13
14    def __str__(self):
15        return "The given parameter {} is of type {} and not int.".format(self.value, \
16 self.value_type)
17
18 class MyNegativeError(MyValueError):
19    def __str__(self):
20        return "The given number {} is not positive.".format(self.value)
21
22 def positive(num):
23     if type(num).__name__ == 'float':
24         raise MyFloatError(num)
25
26     if type(num).__name__ != 'int':
27         raise MyTypeError(num, type(num).__name__)
28
29     if num < 0:
30         raise MyNegativeError(num)
31
32 for val in [14, 24.3, "hi", -10]:
33     print(val)
```

```
34     print(type(val).__name__)
35     try:
36         positive(val)
37     except MyValueError as ex:
38         print("Exception: {}".format(ex))
39         print("Exception type {}".format(type(ex).__name__))
40
41     # Exception, ValueError
```

Exception finally return

```
1  def div(a, b):
2      try:
3          print("try")
4          c = a / b
5      except Exception:
6          print("exception")
7          return
8      finally:
9          print("finally")
10
11  div(2, 1)
12  print('---')
13  div(2, 0)
```

Warnings

Warnings

```
1  from warnings import warn
2
3  def foo():
4      warn("foo will be deprecated soon. Use bar() instead", DeprecationWarning)
5      print("foo still works")
6
7
8  def main():
9      foo()
10     print("afterfoo")
11
12  main()
```

CSV

Reading CSV the naive way

```
1 Tudor;Vidor;10;Hapci
2 Szundi;Morgo;7;Szende
3 Kuka;Hofeherke;100;Kiralyno
4 Boszorkany;Herceg;9;Meselo
```

```
1 import sys, csv
2
3 if len(sys.argv) != 2:
4     sys.stderr.write("Usage: {} FILENAME\n".format(sys.argv[0]))

5  Terry,Jones,1 February 1942
6  John,Cleese,27 October 1939
7  Michael,Palin,5 May 1943

```

```

1  import csv
2
3  file = 'examples/csv/monty_python.csv'
4  with open(file) as fh:
5      rd = csv.DictReader(fh, delimiter=',')
6      for row in rd:
7          print(row)

```

```

1  {'lname': 'Chapman', 'born': '8 January 1941', 'fname': 'Graham'}
2  {'lname': 'Idle', 'born': '29 March 1943', 'fname': 'Eric'}
3  {'lname': 'Gilliam', 'born': '22 November 1940', 'fname': 'Terry'}
4  {'lname': 'Jones', 'born': '1 February 1942', 'fname': 'Terry'}
5  {'lname': 'Cleese', 'born': '27 October 1939', 'fname': 'John'}
6  {'lname': 'Palin', 'born': '5 May 1943', 'fname': 'Michael'}

```

Exercise: CSV

Given the CSV file of Monty Python troupe, create a dictionary where we can look up information about them based on the first name. For example:

```

1  people = read_csv_file()
2  print(people["Graham"]["lname"]) # Champman
3  print(people["John"]["born"])    # 27 October 1939
4  print(people["Michael"])
5      # {'lname': 'Palin', 'born': '5 May 1943', 'fname': 'Michael'}
6  print(people["Terry"]["lname"]) # Gilliam

```

For extra bonus create another dictionary where we can look up the information based on their fname and lname.

Solution: CSV

```
1  import csv
2
3  def read_csv_file():
4      file = 'examples/csv/monty_python.csv'
5      name_of = {}
6      with open(file) as fh:
7          rd = csv.DictReader(fh, delimiter=',')
8          for row in rd:
9              name_of[ row['fname'] ] = row
10     print(name_of)
11     return name_of
12
13 people = read_csv_file()
14 print(people["Graham"]["lname"])  # Chapman
15 print(people["John"]["born"])    # 27 October 1939
16 print(people["Michael"])
17     # {'lname': 'Palin', 'born': '5 May 1943', 'fname': 'Michael'}
18 print(people["Terry"]["lname"])  # Gilliam
```

Excel

Spreadsheets

- CSV files - use the standard csv library
- Microsoft Excel files (various versions and formats)
- Open Office / Libre Office Calc

Python Excel

- [Python Excel](#)¹⁴¹
- [openpyxl](#)¹⁴²
- [xlsxwriter](#)¹⁴³
- [xlrd](#)¹⁴⁴
- [xlwt](#)¹⁴⁵
- [xlutils](#)¹⁴⁶ using xlrd and xlwt. Mostly obsolete.

Create an Excel file from scratch

```
1  import openpyxl
2  import datetime
3
4  wb = openpyxl.Workbook()
5
6  ws = wb.active
7
8  ws['A1'] = 42
9
10 ws['A2'] = datetime.datetime.now()
11 #ws.column_dimensions['A'].width = 20.0
12
13 wb.save("first.xlsx")
```

¹⁴¹<http://www.python-excel.org/>

¹⁴²<https://openpyxl.readthedocs.org/>

¹⁴³<https://xlsxwriter.readthedocs.org/>

¹⁴⁴<http://xlrd.readthedocs.io/>

¹⁴⁵<http://xlrd.readthedocs.io/>

¹⁴⁶<http://xlutils.readthedocs.io/>

Worksheets in Excel

```
1 import openpyxl
2 import datetime
3
4 wb = openpyxl.Workbook()
5 ws = wb.active
6 ws['A1'] = 42
7 ws.title = "First"
8
9 ws2 = wb.create_sheet()
10 ws2.title = "Second sheet"
11 ws2['A1'] = datetime.datetime.now()
12 ws2.sheet_properties.tabColor = "1072BA"
13
14 wb.save("two_worksheets.xlsx")
```

Add expressions to Excel

Nothing special needed.

```
1 import openpyxl
2 import datetime
3
4 wb = openpyxl.Workbook()
5
6 ws = wb.active
7
8 ws['A1'] = 19
9 ws['A2'] = 23
10
11 ws['A3'] = "=A1+A2"
12
13 wb.save("expression.xlsx")
```

Format field

```

1  import openpyxl
2  import datetime
3
4  wb = openpyxl.Workbook()
5
6  ws = wb.active
7
8  ws['A1'] = 123456.78
9  ws['A2'] = 123456.78
10 ws['A3'] = 123456.78
11 ws['A4'] = -123456.78
12 ws['A5'] = datetime.datetime.now()
13 ws.column_dimensions['A'].width = 20.0
14
15 ws['A2'].number_format = '0.00E+00'
16 ws['A3'].number_format = '#,##0_);[RED](#,##0)'
17 ws['A4'].number_format = '#,##0_);[RED](#,##0)'
18
19 wb.save("format.xlsx")

```

Number series and chart

```

1  import openpyxl
2
3  wb = openpyxl.Workbook()
4
5  ws = wb.active
6  ws.title = "Chart"
7
8  a = ["First", 20, 28, 30, 37, 18, 47]
9  b = ["Second", 35, 30, 40, 40, 38, 35]
10
11 # write them as columns
12 for i in range(len(a)):
13     ws.cell(row=i+1, column=1).value = a[i]
14     ws.cell(row=i+1, column=2).value = b[i]
15
16 lc = openpyxl.chart.LineChart()
17 lc.title = "Two Lines Chart"
18 #lc.style=13
19 data = openpyxl.chart.Reference(ws,
20                                min_col=1,

```

```
21             min_row=1,
22             max_col=2,
23             max_row=len(a))
24 lc.add_data(data, titles_from_data=True)
25
26 ws.add_chart(lc, "D1")
27 wb.save("chart.xlsx")
```

Read Excel file

```
1 import openpyxl
2 wb = openpyxl.load_workbook(filename = 'chart.xlsx')
3 for ws in wb.worksheets:
4     print(ws.title)
5
6 ws = wb.worksheets[0]
7 print(ws['A1'].value)
```

Update Excel file

```
1 import openpyxl
2
3 wb = openpyxl.load_workbook(filename = 'chart.xlsx')
4 for ws in wb.worksheets:
5     print(ws.title)
6
7 ws = wb.worksheets[0]
8 c = ["Third", 40, 20, 35, 25, 20, 35]
9
10 for i in range(len(c)):
11     ws.cell(row=i+1, column=3).value = c[i]
12
13 lc = openpyxl.chart.LineChart()
14 lc.title = "Three Lines Chart"
15 data = openpyxl.chart.Reference(ws,
16                                 min_col=1,
17                                 min_row=1,
18                                 max_col=3,
19                                 max_row=len(c))
20 lc.add_data(data, titles_from_data=True)
21
```

```
22 ws.add_chart(1c, "D1")
23
24 wb.save("chart.xlsx")
```

Exercise: Excel

- Create a series of 10 random numbers between 1 and 100 and save them in an Excel file in a column.
- Create a graph showing the values.
- Add a second series of 10 random numbers, add them to the Excel file as a second column next to the first one.
- Add a 3rd column containing the average of the first two columns.
- Update the graph to include all 3 number serieses

XML

XML Data

3  what_is_this = Seq("AGTC_U")
4  what_is_this.complement() # ValueError: Mixed RNA/DNA found

```

Download data

Use the NCBI (National Center for Biotechnology Information) database to search manually for [nucleotide](#)¹⁸⁷ or tons of other types of data. Then one can download the files manually from the web site.

Read FASTA, GenBank files

For example the data about Orchids in two formats:

- [ls_orchid.fasta](#)¹⁸⁸ in FASTA format
- [ls_orchid.gbk](#)¹⁸⁹ in GenBank format

Download those files and use them:

```

1  from Bio import SeqIO
2  import requests
3
4  def get_file(url, filename):
5      res = requests.get(url)
6      if res.status_code != 200:
7          raise Exception("Could not get file")
8
9      with open(filename, 'w') as fh:
10         fh.write(res.text)
11
12
13  def process_file(filename, file_type):
14      for seq_record in SeqIO.parse(filename, file_type):
15          print(seq_record.id)
16          print(repr(seq_record.seq))
17          print(len(seq_record))

```

¹⁸⁷<https://www.ncbi.nlm.nih.gov/nucleotide>

¹⁸⁸https://raw.githubusercontent.com/biopython/biopython/master/Doc/examples/ls_orchid.fasta

¹⁸⁹https://raw.githubusercontent.com/biopython/biopython/master/Doc/examples/ls_orchid.gbk

```

18
19
20 fasta_url = 'https://raw.githubusercontent.com/biopython/biopython/master/Doc/examples/ls_orchid.fasta'
21
22 filename = "ls_orchid.fasta"
23 file_type = "fasta"
24 get_file(fasta_url, filename)
25 process_file(filename, file_type)
26
27
28 genbank_url = "https://raw.githubusercontent.com/biopython/biopython/master/Doc/examples/ls_orchid.gbk"
29
30 filename = "ls_orchid.gbk"
31 file_type = "genbank"
32 get_file(genbank_url, filename)
33 process_file(filename, file_type)

```

Search nucleotids

You can also search the same database programmatically.

```

1 from Bio import Entrez
2 Entrez.email = "gabor@szabgab.com"
3
4 term = "Cyripedioideae[Orgn] AND matK[Gene]"
5
6 handle = Entrez.esearch(db="nucleotide", term=term, idtype="acc", retmax=30)
7 record = Entrez.read(handle)
8 print(record["Count"])          # 538
9 print(record["IdList"])         # ['MK792700.1', 'MK792699.1', 'MK792698.1', ..., 'MK79\
10 2681.1']
11 print(len(record["IdList"]))    # 30
12 handle.close()
13
14
15 # term = "Orchid"
16 # 530077
17 # ['NZ_SEL000000000.2', 'NZ_SEL02000072.1',

```

Download nucleotids

```
1  from Bio import Entrez, SeqIO
2
3  Entrez.email = "gabor@szabgab.com"
4
5  #doc_id = 'MK792700.1'
6  doc_id = "EU490707"
7
8  # rettype="fasta"
9  handle = Entrez.efetch(db="nucleotide", id=doc_id, rettype="gb", retmode="text")
10 data = handle.read()
11 handle.close()
12 #print(data)
13
14 filename = "temp.data"
15 with open(filename, 'w') as fh:
16     fh.write(data)
17
18 file_type = "genbank"
19 for seq_record in SeqIO.parse(filename, file_type):
20     print(seq_record.id)
21     print(repr(seq_record.seq))  # A short part of the sequence
22     print()
23     print(seq_record.seq)      # The full sequence
24     print()
25     print(len(seq_record.seq))
26     print()
27     print(seq_record.name)
28     print()
29     print(seq_record.annotations)
30     #print()
31     #print(dir(seq_record))
```

Exercise: Nucleotid

- Search for your favorite nucleotid
- Print out the number of results
- Download the 3 different sequences from the list (using the id) in GeneBank format and save them in files using the id as the name of the file and .gb as the extension
- Write a separate script that reads and displays the sequences.

Plot, scatter, histogram

- plot - line
- scatter - just the values
- histogram (to group the values into bins)
- plt.hist(data, bin=10)

Seaborn

Seaborn use examples

seaborn²²⁹

In Jupyter notebook type `%matplotlib` before writing the seaborn code.

In plain Python import `matplotlib`, then assign the result of the plotting function to a variable, and call `matplotlib.pyplot.show(r)`.

Seaborn tip

```
1  """
2  Source : https://seaborn.pydata.org/introduction.html
3  """
4
5  import seaborn as sns
6
7  sns.set() # Apply the default default seaborn theme, scaling, and color palette. Op\
8  tional.
9
10 tips = sns.load_dataset("tips") # Load example dataset into Pandas DataFrame
11 #print(type(tips))
12
13 # print(tips)
14
15 plot = sns.relplot(
16     x = "total_bill",
17     y = "tip",
18     col = "time",
19     hue = "smoker",
20     style = "smoker",
21     size = "size",
22     data = tips)
23
24 # print(type(plot)) # seaborn.axisgrid.FacetGrid
25 plot.savefig("tips.png")
```

²²⁹<https://seaborn.pydata.org/>

Seaborn Anscombes Quartet

```

1  """
2  Anscombe's quartet
3  =====
4
5  _thumb: .4, .4
6
7  Source: https://seaborn.pydata.org/examples/anscombes\_quartet.html
8  """
9  import seaborn as sns
10 import matplotlib
11 sns.set(style="ticks")
12
13 # Load the example dataset for Anscombe's quartet
14 df = sns.load_dataset("anscombe")
15
16 # Show the results of a linear regression within each dataset
17 r = sns.lmplot(
18     x="x",
19     y="y",
20     col="dataset",
21     hue="dataset",
22     data=df,
23     col_wrap=2,
24     ci=None,

```

```
25     palette="muted",
26     height=4,
27     scatter_kws={"s": 50, "alpha": 1})
28
29 matplotlib.pyplot.show(r)
```

Jupyter notebooks

Jupyter on Windows

On Windows install [Anaconda](#)²³⁰ and then you'll be able to run Jupyter notebook from the start menu.

Jupyter on Linux and OSX

Install

For Linux and OSX I recommend using **virtualenv** and installing with **pip**.

```
1 virtualenv -p python3 ~/venv3
2 source ~/venv3/bin/activate
3 pip install jupyter
```

Run

```
1 cd examples/jupyter/
2 jupyter notebook
```

- Your browser should open. If not, there is a link in the terminal.

Jupyter add

- Open an existing notebook (ipynb file). e.g examples/jupyter/add.ipynb
- Create new notebook.
- File - Save As
- ...
- Quit - shut down the notebook server.

²³⁰<https://www.anaconda.com/distribution/>

```
1 def add(x, y):
2     return x+y
3
4 add(2,3)
```

Planets

```
1 Planet name,Distance (AU),Mass
2 Mercury,0.4,0.055
3 Venus,0.7,0.815
4 Earth,1,1
5 Mars,1.5,0.107
6 Ceres,2.77,0.00015
7 Jupiter,5.2,318
8 Saturn,9.5,95
9 Uranus,19.6,14
10 Neptune,30,17
11 Pluto,39,0.00218
12 Charon,39,0.000254
```

Testing

Traditional Organizations

- Months of planning
- Many months of development
- Many months of testing / qa
- Release once every few months or once a year
- (Waterfall)

Quality Assurance

- Nightly build
- Testing new features
- Testing bug fixes
- Maybe testing critical features again and again...
- ...or maybe not.
- Regression testing?
- Testing / qa has a huge boring repetitive part.
- It is also very slow and expensive.

Web age Organizations

- Very frequent releases (20-30 / day!)
- Very little time for manual testing
- CI - Continuous Integration
- CD - Continuous Delivery
- CD - Continuous Deployment

TDD vs Testing as an Afterthought

- TDD - Test Driven Development.

*

- Testing as an afterthought:
- Exiting product
- Mostly works
- Hard to test

Why test?

- Business Value
- Avoid regression
- Better Software Design (TDD)
- Your Sanity

Testing Modes

- Functional testing
- Unit testing
- Integration testing
- Acceptance testing (BDD Behavior-driven development?)
- White box
- Black box
- Regression testing
- Usability testing
- Performance testing
- Load testing
- Security testing
- ...

Testing Applications

- Web site
- Web application
- Web API / Microservice (JSON, XML)
- Mobile Application
- Desktop Application (GUI)
- Command-line tool (CLI)
- Batch process

Testing What to test?

- How would you check that they work as expected?
- What if they get invalid input?
- Edge cases? (e.g. 0, -1, 131314134141)
- A value that is too big or too small.
- Invalid or no response from third-party system.

Testing in Python

- Doctest
- Unittest
- Pytest
- Nose
- Nimoy
- Hypothesis
- Selenium
- Tox

Testing Environment

- Git (or other VCS)
- Virtualenv
- Docker
- ...

Testing Setup - Fixture

- Web server
- Databases
- Other machines
- Devices
- External services

Testing Resources

²³⁴<http://www.angryweasel.com/ABTesting/>

Testing with unittest

Use a module

We have a module called `mymath` that has two methods: `add` and `div`.

```
1 import mymath
2 print( mymath.add(2, 3) )
3 print( mymath.div(6, 2) )
```

```
1 import mymath
2 import sys
3
4 if len(sys.argv) != 4:
5     exit("Usage: {} [add|div] INT INT".format(sys.argv[0]))
6
7 if sys.argv[1] == 'add':
8     print(mymath.add(int(sys.argv[2]), int(sys.argv[3])))
9 if sys.argv[1] == 'div':
10    print(mymath.div(int(sys.argv[2]), int(sys.argv[3])))
```

Test a module

```
1 import unittest
2 import mymath
3
4 class TestMath(unittest.TestCase):
5
6     def test_math(self):
7         self.assertEqual(mymath.add(2, 3), 5)
8         self.assertEqual(mymath.div(6, 3), 2)
9         self.assertEqual(mymath.div(42, 1), 42)
10        self.assertEqual(mymath.add(-1, 1), 0)
11
12 if __name__ == '__main__':
13     unittest.main()
```

The tested module

```
1 def add(x, y):
2     """Adding two numbers
3
4     >>> add(2, 3)
5     5
6
7     """
8     return x + y
9
10 def div(x, y):
11     """Dividing two numbers
12
13     >>> div(8, 2)
14     4
15     >>> div(8, 0)
16     Traceback (most recent call last):
17     ...
18     ZeroDivisionError: integer division or modulo by zero
19
20     """
21     return x / y
22
23
24 #print add(2, 3, 4)
```

Testing - skeleton

```
1 import unittest
2
3 def add(x, y):
4     return x+y
5
6 class Something(unittest.TestCase):
7
8     def setUp(self):
9         pass
10        #print("setup")
11
12    def tearDown(self):
```

```
13     pass
14     #print("teardown")
15
16     def test_something(self):
17         self.assertEqual(add(2, 3), 5)
18         self.assertEqual(add(0, 3), 3)
19         self.assertEqual(add(0, 3), 2)
20
21
22     def test_other(self):
23         self.assertEqual(add(-3, 3), 0)
24         self.assertEqual(add(-3, 2), 7)
25         self.assertEqual(add(-3, 2), 0)
26
27
28 if __name__ == '__main__':
29     unittest.main()
```

Testing

```
1  import unittest
2
3  class TestReg(unittest.TestCase):
4
5      def setUp(self):
6          self.str_number = "123"
7          self.str_not_number = "12x"
8
9      def test_match1(self):
10         self.assertEqual(1, 1)
11         self.assertRegexpMatches(self.str_number, r'^\d+$')
12
13     def test_match2(self):
14         self.assertEqual(1, 1)
15         self.assertRegexpMatches(self.str_not_number, r'^\d+$')
16
17 if __name__ == '__main__':
18     unittest.main()
19
```

Testing with PyTest

Pytest features

- Organize and run test per directory (test discovery)
- Run tests by name matching
- Run tests by mark (smoke, integration, db)
- Run tests in parallel with the xdist plugin.
- Create your own fixtures and distribute them.
- Create your own plugins and distribute them.

Pytest setup

Python 2

```
1 virtualenv venv2
2 source venv2/bin/activate
3 pip install pytest
```

Python 3

```
1 virtualenv venv3 -p python3
2 source venv3/bin/activate
3 pip install pytest
```

Python 3 Debian/Ubuntu

```
1 apt-get install python3-pytest
```

Python 3 RedHat/Centos

```
1 yum install python3-pytest
```

Testing with Pytest

A module called `mymath` with two functions: `add` and `div`.

```
1 def add(x, y):
2     """Adding two numbers
3
4     >>> add(2, 3)
5     5
6
7     """
8     return x + y
9
10 def div(x, y):
11     """Dividing two numbers
12
13     >>> div(8, 2)
14     4
15     >>> div(8, 0)
16     Traceback (most recent call last):
17     ...
18     ZeroDivisionError: integer division or modulo by zero
19
20     """
21     return x / y
```

Testing functions

```
1 import mymath
2
3 def test_math():
4     assert mymath.add(2, 3) == 5
5     assert mymath.div(6, 3) == 2
6     assert mymath.div(42, 1) == 42
7     assert mymath.add(-1, 1) == 0
```

Testing class and methods

```

1  import mymath
2
3  class TestMath():
4      def test_math(self):
5          assert mymath.add(2, 3) == 5
6          assert mymath.div(6, 3) == 2
7          assert mymath.div(42, 1) == 42
8          assert mymath.add(-1, 1) == 0

```

Pytest - execute

```

```

Exercise: test math functions

- Test methods of the [math](https://docs.python.org/3/library/math.html)²³⁷ module.
- `ceil`
- `factorial`
- `gcd`

Exercise: test this app

Write tests for the `swap` and `average` functions of the `app` module. Can you find a bug?

²³⁷<https://docs.python.org/3/library/math.html>

```
1 def swap(txt):
2     '''
3     >>> half("abcd")
4     cdab
5     '''
6     return txt[int(len(txt)/2):] + txt[:int(len(txt)/2)]
7
8 def average(*numbers):
9     '''
10    >>> average(2, 4, 6)
11    4
12    '''
13    s = 0
14    c = 0
15    for n in numbers:
16        s += n
17        c += 1
18    return s/c
```

Exercise: test the csv module

- [csv](#)²³⁸
- Create a CSV file, read it and check if the results are as expected!
- Test creating a CSV file?
- Test round trip?

Solution: Pytest test math functions

```
1 import math
2
3 def test_gcd():
4     assert math.gcd(6, 9) == 3
5     assert math.gcd(17, 9) == 1
6
7 def test_ceil():
8     assert math.ceil(0) == 0
9     assert math.ceil(0.1) == 1
10    assert math.ceil(-0.1) == 0
11
```

²³⁸<https://docs.python.org/3/library/csv.html>

```

12 def test_factorial():
13     assert math.factorial(0) == 1
14     assert math.factorial(1) == 1
15     assert math.factorial(2) == 2
16     assert math.factorial(3) == 6

1 import math
2 import pytest
3
4 def test_math():
5     with pytest.raises(Exception) as exinfo:
6         math.factorial(-1)
7     assert exinfo.type == ValueError
8     assert str(exinfo.value) == 'factorial() not defined for negative values'
9
10
11     with pytest.raises(Exception) as exinfo:
12         math.factorial(1.2)
13     assert exinfo.type == ValueError
14     assert str(exinfo.value) == 'factorial() only accepts integral values'

```

Solution: Pytest test this app

```

1 import app
2
3 def test_swap():
4     assert app.swap("abcd") == "cdab"
5     assert app.swap("abc") == "bca"
6     assert app.swap("abcde") == "cdeab"
7     assert app.swap("a") == "a"
8     assert app.swap("") == ""
9
10 def test_average():
11     assert app.average(2, 4) == 3
12     assert app.average(2, 3) == 2.5
13     assert app.average(42) == 42
14     #assert app.average() == 0

```

Solution: test the csv module

```

1 Tudor;Vidor;10;Hapci
2 Szundi;Morgo;7;Szende
3 Kuka;"Hofeherke;
4 alma";100;Kiralyno
5 Boszorkany;Herceg;9;Meselo

```

```

1 import csv
2
3
4 def test_csv():
5     filename = '../examples/csv/process_csv_file_newline.csv'
6     with open(filename) as fh:
7         rd = csv.reader(fh, delimiter=';')
8         assert rd.__next__() == ['Tudor', 'Vidor', '10', 'Hapci']
9         assert rd.__next__() == ['Szundi', 'Morgo', '7', 'Szende']
10        assert rd.__next__() == ['Kuka', 'Hofeherke; \nalma', '100', 'Kiralyno']
11        assert rd.__next__() == ['Boszorkany', 'Herceg', '9', 'Meselo']

```

PyTest bank deposit

```

1 class NegativeDeposit(Exception):
2     pass
3
4 class Bank:
5     def __init__(self, start):
6         self.balance = start
7
8     def deposit(self, money):
9         if money < 0:
10            raise NegativeDeposit('Cannot deposit negative sum')
11            self.balance += money
12            return

```

PyTest expected exceptions (bank deposit)

```

1  import pytest
2  from banks import Bank, NegativeDeposit
3
4
5  def test_negative_deposit():

```

PyTest Fixtures

- In generally we call [test fixture](https://en.wikipedia.org/wiki/Test_fixture)²³⁹ the environment in which a test is expected to run.
- Pytest uses the same word for a more generic concept. All the techniques that make it easy to set up the environment and to tear it down after the tests.

PyTest Fixture setup and teardown

²³⁹https://en.wikipedia.org/wiki/Test_fixture

```
1 def setup_module():
2     print("setup_module")
3
4 def teardown_module():
5     print("teardown_module")
6
7
8 def setup_function():
9     print("  setup_function")
10
11 def teardown_function():
12     print("  teardown_function")
13
14
15 def test_one():
16     print("    test_one")
17     assert True
18     print("    test_one after")
19
20 def test_two():
21     print("    test_two")
22     assert False
23     print("    test_two after")
24
25 def test_three():
26     print("    test_three")
27     assert True
28     print("    test_three after")
```

See next slide for the output.

PyTest Fixture setup and teardown output

```
1 test_fixture.py .F.
```

```
1 $ pytest test_fixture.py -s
2
3 setup_module
4
5     setup_function
6         test_one
7         test_one after
8     teardown_function
9
10    setup_function
11        test_two
12    teardown_function
13
14    setup_function
15        test_three
16        test_three after
17    teardown_function
18
19 teardown_module
```

Note, the `teardown_function` is executed even after failed tests.

PyTest: Class setup and teardown

```
1 class TestClass():
2     def setup_class(self):
3         print("setup_class called once for the class")
4
5     def teardown_class(self):
6         print("teardown_class called once for the class")
7
8
9     def setup_method(self):
10        print("setup_method called for every method")
11
12    def teardown_method(self):
13        print("teardown_method called for every method")
14
15
16    def test_one(self):
17        print("one")
18        assert True
```

```
19         print("one after")
20
21     def test_two(self):
22         print("two")
23         assert False
24         print("two after")
25
26     def test_three(self):
27         print("three")
28         assert True
29         print("three after")
```

PyTest: Class setup and teardown output

```
1  $ pytest -s test_class.py
2
3  setup_class called once for the class
4
5  setup_method called for every method
6  one
7  one after
8  teardown_method called for every method
9
10 setup_method called for every method
11 two
12 teardown_method called for every method
13
14 setup_method called for every method
15 three
16 three after
17 teardown_method called for every method
18
19 teardown_class called once for the class
```

Pytest Dependency injection

```
1 def function(thingy):
2     pass
```

1. Find function.
2. Check parameters of the function.

3. Create the appropriate instances.
4. Call the function with the instances.

Pytest fixture - tmpdir

```
1 import os
2
3
4 def test_something(tmpdir):
5     print(tmpdir)          # /private/var/folders/ry/z60xxmw0000gn/T/pytest-of-gabor/pyt\
6 est-14/test_read0
7
8     d = tmpdir.mkdir("subdir")
9     fh = d.join("config.ini")
10    fh.write("Some text")
11
12    filename = os.path.join( fh.dirname, fh.basename )
13
14    temp_dir = str(tmpdir)
15
16    # ...
```

Pytest capture STDOUT and STDERR with capsys

Captures everything that is printed to STDOUT and STDERR so we can compare that to the expected output and error.

```
1 import sys
2
3 def greet(to_out, to_err=None):
4     print(to_out)
5     if to_err:
6         print(to_err, file=sys.stderr)
7
8
9 def test_myoutput(capsys):
10    greet("hello", "world")
11    out, err = capsys.readouterr()
12    assert out == "hello\n"
13    assert err == "world\n"
14
```

```
15     greet("next")
16     out, err = capsys.readouterr()
17     assert out == "next\n"
```

Pytest Fixture - home made fixtures

```
1  import pytest
2  import application
3
4
5  @pytest.fixture()
6  def getapp():
7      print('getapp starts')
8      app = application.App()
9
10     yield app
11
12     app.shutdown()
13     print('getapp ends')
14
15 def test_add_user_foo(getapp):
16     getapp.add_user("Foo")
17     assert True
18
19 def test_add_user_bar(getapp):
20     getapp.add_user("Bar")
21     assert True
```

```
1  class App:
2      def __init__(self):
3          self.pi = 3.14
4          # .. set up database
5          print("__init__ of App")
6
7
8      def shutdown(self):
9          print("shutdown of App cleaning up database")
10
11
12      def add_user(self, name):
13          print("Working on add_user({})".format(name))
```

```
1 $ pytest -s -q fixtures.py
2
3 getapp starts
4 __init__ of App
5 Working on add_user(Bar)
6 .shutdown of App cleaning up database
7 getapp ends
8
9 getapp starts
10 __init__ of App
11 Working on add_user(Foo)
12 .shutdown of App cleaning up database
13 getapp ends
```

```

- We can't add fixtures to test_functions as decorators (as I think was the case in NoseTest), we need to use dependency injection.

Pytest: Mocking - why?

- Independent testing environment.
- Faster tests (mock remote calls, mock whole database)
- Fake some code/application/API that does not exist yet.
- Test error conditions in a system not under our control.

Pytest: Mocking - what?

- External dependency (e.g. an API)
- STDIN/STDOUT/STDERR
- Random values
- Methods of a database

Pytest: One dimensional spacefight

```

1  import random
2
3  def play():
4      debug = False
5      move = False
6      while True:
7          print("\nWelcome to another Number Guessing game")

```

PyTest: Run tests in parallel with xdist

```

1         $ pip install pytest-xdist
2         $ pytest -n NUM

```

PyTest: Order of tests

Pytest runs the test in the same order as they are found in the test module:

```

1 def test_one():
2     assert True
3
4 def test_two():
5     assert True
6
7 def test_three():
8     assert True

```

```

1 test_order.py::test_one PASSED
2 test_order.py::test_two PASSED
3 test_order.py::test_three PASSED

```

PyTest: Randomize Order of tests

Install `pytest-random-order`²⁴⁰

```

1 pip install pytest-random-order

```

And from now on all the test will run in a random order.

PyTest: Force default order

If for some reason we would like to make sure the order remains the same, we can add the following two lines of code.

²⁴⁰<https://pypi.python.org/pypi/pytest-random-order>

```
1 import pytest
2 pytestmark = pytest.mark.random_order(disabled=True)

1 import pytest
2 pytestmark = pytest.mark.random_order(disabled=True)
3
4 def test_one():
5     assert True
6
7 def test_two():
8     assert True
9
10 def test_three():
11     assert True
```

PyTest: no random order

```
1 pytest -p no:random-order -v
```

Anagram on the command line

```
1 from mymod_1 import is_anagram
2 import sys
3
4 if len(sys.argv) != 3:
5     exit("Usage {} STR STR".format(sys.argv[0]))
6
7 print(is_anagram(sys.argv[1], sys.argv[2]))
```

PyTest testing CLI

```
1  import subprocess
2
3  def capture(command):
4      proc = subprocess.Popen(command,
5                              stdout = subprocess.PIPE,
6                              stderr = subprocess.PIPE,
7                              )
8      out,err = proc.communicate()
9      return out, err, proc.returncode
10
11
12 def test_anagram_no_param():
13     command = ["python3", "examples/pytest/anagram.py"]
14     out, err, exitcode = capture(command)
15     assert exitcode == 1
16     assert out == b''
17     assert err == b'Usage examples/pytest/anagram.py STR STR\n'
18
19 def test_anagram():
20     command = ["python3", "examples/pytest/anagram.py", "abc", "cba"]
21     out, err, exitcode = capture(command)
22     assert exitcode == 0
23     assert out == b'True\n'
24     assert err == b''
25
26 def test_no_anagram():
27     command = ["python3", "examples/pytest/anagram.py", "abc", "def"]
28     out, err, exitcode = capture(command)
29     assert exitcode == 0
30     assert out == b'False\n'
31     assert err == b''
```

PyTest test discovery

Running `py.test` will find test files and in the files test functions.

- `test_*.py` files
- `*_test.py` files
- `test_*` functions
- ...

```

```

No test selected

If you run pytest and it cannot find any tests, for example because you used some selector and not test matched it, then Pytest will exit with exit code 5.

This is considered a failure by every tool, including Jenkins and other CI systems.

On the other hand you won't see any failed test reported. After all if no tests are run, then none of them fails.

This can be confusing.

²⁵⁴<https://pypi.org/project/pytest-json-report/>

Advanced functions

Variable scopes

- Local (inside a def)
- Enclosing (in the enclosing def, aka. nonlocal)
- Global (outside of all defs)

Name resolution order (LEGB)

1. Local
2. Enclosing
3. Global
4. Built-in

Scoping: global seen from function

```
1 a = 42
2 def f():
3     print(a)
4
5 f()
```

42

Assignment creates local scope

```
1 a = 42
2 def f():
3     a = 23
4     print(a)
5
6 print('ok')
7 print(a)
8 f()
9 print(a)
```

```
1 ok
2 42
3 23
4 42
```

Local scope gone wrong

```
1 a = 42
2 def f():
3     print(a)
4     a = 23
5
6 print('ok')
7 print(a)
8 f()
9 print(a)
```

```
1 ok
2 42
3 Traceback (most recent call last):
4   File "scoping_external_variable.py", line 8, in <module>
5     f()
6   File "scoping_external_variable.py", line 3, in f
7     print(a)
8 UnboundLocalError: local variable 'a' referenced before assignment
```

Accessing a global variable inside a function works, but if I change it (make it refer to another piece of data), then it is disallowed. If I only change the data inside (for mutable variables), that works, but is a bad practice.

Changing global variable from a function

```
1 a = 42
2 def f():
3     global a
4     print(a)
5     a = 23
6
7 print(a)    # 42
8 f()        # 42
9 print(a)    # 23
```

Does not need to be created outside

```
1 def f():
2     global a
3     a = 23
4
5 f()
6 print(a)    # 23
```

Global variables mutable in functions

```
1 a = [2]
2
3 def f():
4     print(a)    # [2]
5     a.append(3)
6     print(a)    # [2, 3]
7     a[0] = 4
8
9 f()
10 print(a)       # [4, 3]
```

Scoping issues

```
1 text = ['aaaa', 'bb', 'ccc ccc']
2
3 length_1 = [ len(s) for s in text ]
4 print(length_1) # [4, 2, 7]
5
6
7 length_2 = [ len(s) for x in text ]
8 print(length_2) # [7, 7, 7]
```

List comprehensions don't create their own scope!

sub in sub

Functions can be defined inside functions.

```
1 def f():
2     print("in f")
3     def g():
4         print("in g")
5     g()
6
7 f()
8 #g() # does not exist here
```

They are scoped locally

Scoping sub in sub (enclosing scope)

```
1 def external_func():
2     the_answer = 42
3
4     def func(args):
5         print(args, "the_answer:", the_answer)
6
7         # the_answer = 'what was the question?'
8         # enabling this would give:
9         # UnboundLocalError: local variable 'the_answer'
10        #     referenced before assignment
11
12    func("first")
```

```
13     func("second")
14
15 external_func()

1 first the_answer: 42
2 second the_answer: 42
```

Function objects

```
1 The difference between
2 x = foo
3 y = foo()

1 c = 0
2
3 def foo():
4     global c
5     c += 1
6     return c
7
8
9 print(foo())    # 1
10 print(foo())   # 2
11 x = foo        # assigning the function object
12 y = foo()      # assigning the return value of the function
13 print(foo())   # 4
14 print(x())     # 5
15 print(y)      # 3
```

Functions are created at run time

def and class are run-time
Everything is runtime. Even compilation is runtime.

foo() will return a random value every time, but when
bar is defined it freezes the specific value that foo
returned when bar was created.

```
1 import random
2
3 def foo():
4     return random.random()
5
6
7 print(foo())
8 print(foo())
9
10 def bar(a, b = foo()):
11     return [a, b]
12
13 print(bar(1))
14 print(bar(2))
```

```
1 0.0756804810689
2 0.350692064113
3 [1, 0.7401995987184571]
4 [2, 0.7401995987184571]
```

Mutable default

The default list assigned to `b` is created when the `f` functions is defined. After that, each call to `f()` (that does not get a “`b`” parameter) uses this common list.

```
1 def f(a, b = []):
2     b.append(a)
3     return b
4
5 print(f(1))
6 print(f(2))
7 print(f(3))
```

```
1 [1]
2 [1, 2]
3 [1, 2, 3]
```

Use `None` instead:

Use `None` as default parameter

```
1 def f(a, b = None):
2     if b == None:
3         b = []
4     b.append(a)
5     return b
6
7 print(f(1))
8 print(f(2))
9 print(f(3))
```

```
1 [1]
2 [2]
3 [3]
```

Inner function created every time the outer function runs

Also defined during run-time, but in every call of bar() the inner_func is redefined again and again.

```
1 import random
2
3 def foo():
4     return random.random()
5
6 print(foo())
7 print(foo())
8
9 def bar(a, b = foo()):
10
11     def inner_func(x, y = foo()):
12         return [x, y]
13
14     print('inner', inner_func(a))
15     return [a, b]
16
17 print(bar(1))
18 print(bar(2))
```

```
1 0.821210904648
2 0.925337844251
3 inner [1, 0.9243163421154859]
4 [1, 0.38535850141949013]
5 inner [2, 0.5665772632462458]
6 [2, 0.38535850141949013]
```

Static variable

There are no function-level static variables in Python, but you can fake it quite easily

```
1 def counter():
2     if 'cnt' not in counter.__dict__:
3         counter.cnt = 0
4     counter.cnt += 1
5     return counter.cnt
6
7 print(counter())      # 1
8 print(counter())      # 2
9 print(counter())      # 3
10
11 print(counter.cnt)    # 3
12
13 counter.cnt = 6
14 print(counter())      # 7
```

Static variable in generated function

```
1 def create():
2     def func():
3         func.cnt += 1
4         return func.cnt
5     func.cnt = 0
6     return func
7
8 a = create()
9 b = create()
10 print(a())    # 1
11 print(a())    # 2
12 print(b())    # 1
13 print(a())    # 3
```

```
14
15 b.cnt = 7
16 print(a.cnt) # 3
17 print(b.cnt) # 7
```

Inspect

The `inspect`²⁵⁵ module provides introspection to Python runtime.

`inspect.stack` returns the stack-trace. Element 0 is the deepest (where we called `inspect.stack`).

Each level has several values. A representation of the frame, filename, lineno, subroutine-name.

```
1  import inspect
2  import sys
3
4  level = int(sys.argv[1])
5
6
7  def f():
8      print("in f before g")
9      g()
10     print("in f after g")
11
12  def g():
13      print("in g")
14      PrintFrame()
15
16
17  def PrintFrame():
18      st = inspect.stack()
19
20      frame = st[level][0]
21      info = inspect.getframeinfo(frame)
22      print('__file__:', info.filename)
23      print('__line__:', info.lineno)
24      print('__function__:', info.function)
25
26      print('* file', st[level][1])
27      print('* line', st[level][2])
28      print('* sub', st[level][3])
29
30  f()
```

²⁵⁵<http://docs.python.org/library/inspect.html>

python caller.py 1

```
1 in f before g
2 in g
3 __file__:      caller.py
4 __line__:      15
5 __function__:  g
6 * file caller.py
7 * line 15
8 * sub g
9 in f after g
```

Variable number of function arguments

Python function arguments - a reminder

- Order of parameter
- Arguments with default values are optional (and come at the end of the definition)
- Number of arguments is known at the time of function definition. The only flexibility is provided by the optional arguments.

```
1 def f(a, b = 42):
2     print(a)
3     print(b)
4
5 f(23)
6     # 23
7     # 42
8
9 f(19, 11)
10    # 19
11    # 11
12
13 f(b=7, a=8)
14    # 8
15    # 7
16
17 # f()          # (runtime) TypeError: f() takes at least 1 argument (0 given)
18 # f(1, 2, 3)   # (runtime) TypeError: f() takes at most 2 arguments (3 given)
19 # f(b=10, 23)  # SyntaxError: non-keyword arg after keyword arg
20
21 # def g(a=23, b):
22 #     pass
23 #     SyntaxError: non-default argument follows default argument
```

Functions with unknown number of arguments

- `sum(a, b, c, ...)`

- `reduce(function, a, b, c, ...)`
- `report (function, foo = 23, bar = 19, moo = 70, ...)`
- `report (function, a, b, c, ..., foo = 23, bar = 19, moo = 70, ...)`

Variable length argument list with * and **

```

1 def f(a, b=1, *args, **kwargs):
2     print('a:      ', a)
3     print('b:      ', b)
4     print('args:   ', args)
5     print('kwargs:', kwargs)
6     return a + b
7
8 f(2, 3, 4, 5, c=6, d=7)
9 print()
10 f(2, c=5, d=6)
11 print()
12 f(10)

```

```

1 a:      2
2 b:      3
3 args:   (4, 5)
4 kwargs: {'c': 6, 'd': 7}
5
6 a:      2
7 b:      1
8 args:   ()
9 kwargs: {'c': 5, 'd': 6}
10
11 a:     10
12 b:      1
13 args:   ()
14 kwargs: {}

```

Passing arguments as they were received (but incorrectly)

What if we need to pass the list of individual arguments (or pairs) to another function?

```
1 def f(*args, **kwargs):
2     print('f args: ', args)
3     print('f kwargs: ', kwargs)
4     g(args, kwargs)
5
6 def g(*args, **kwargs):
7     print('g args: ', args)
8     print('g kwargs: ', kwargs)
9
10 f(1, 2, a=3, b=4)
```

```
1 f args:      (1, 2)
2 f kwargs:    {'a': 3, 'b': 4}
3 g args:      ((1, 2), {'a': 3, 'b': 4})
4 g kwargs:    {}
```

g() received 2 individual parameters, the first was a tuple, the second a dictionary

Unpacking args before passing them on

```
1 def f(*args, **kwargs):
2     print('f: ', args)
3     print('f: ', kwargs)
4     g(*args, **kwargs)
5
6 def g(*args, **kwargs):
7     print('g: ', args)
8     print('g: ', kwargs)
9
10 f(1, 2, a=3, b=4)
```

```
1 f:  (1, 2)
2 f:  {'a': 3, 'b': 4}
3 g:  (1, 2)
4 g:  {'a': 3, 'b': 4}
```

Exercise: implement the my_sum function

- my_sum should be able to accept any number of values and return their sum.
- my_sum() should return 0 or None. Decide yourself!
- my_sum(2, 3) should return 5. etc.

Solution: implement the my_sum function

```
1 def my_sum(*numbers):
2     s = 0
3     for n in numbers:
4         s += n
5     return s
6
7 print(my_sum())           # 0
8 print(my_sum(2, 3))      # 5
9 print(my_sum(-1, 2, -1,)) # 0
```

Exercise: implement the reduce function

```
1 my_reduce(function, a, b, c, ...)
```

- 'function' is expected to be a function that receives two arguments and returns a result.
- If only the function is given, return None.
- If only one value is given, return that value.
- Take the first two values, run the function on them. Then take the result and the next value and run the function on them. etc. When no more values are left, return the last result.

```
1 # print(my_reduce()) # TypeError: my_reduce() takes at least 1 argument (0 given)
2 print(my_reduce(lambda x,y: x+y))           # None
3 print(my_reduce(lambda x,y: x+y, 3))        # 3
4 print(my_reduce(lambda x,y: x+y, -1, 4, -2)) # 1
5
6 print(my_reduce(lambda x,y: x*y, -1, 4, -2)) # 8
```

Soluton: implement the reduce function

```

1  def my_reduce(f, *args):
2      if len(args) == 0:
3          return None
4      result = args[0]
5      for i in range(1, len(args)):
6          result = f(result, args[i])
7      return result
8
9  # print(my_reduce()) # TypeError: my_reduce() takes at least 1 argument (0 given)
10 print(my_reduce(lambda x,y: x+y))          # None
11 print(my_reduce(lambda x,y: x+y, 3))        # 3
12 print(my_reduce(lambda x,y: x+y, -1, 4, -2)) # 1
13
14 print(my_reduce(lambda x,y: x*y, -1, 4, -2)) # 8

```

Exercise: sort pairs

Create a function called `sort_pairs`, that would receive a sorting method, e.g. the word 'keys' or the word 'values' and will receive an arbitrary number of key-value pairs and will return a list of tuples.

```

1  sort_pairs( 'keys', foo = 23, bar = 47)
2  [('bar', 47), ('foo', 23)]
3
4  sort_pairs( 'values', foo = 23, bar = 47)
5  [('foo', 23), ('bar', 47)]

```

Solution: sort pairs

```

1  def sort_pairs(how, **kwargs):
2      if how == 'keys':
3          sort_function = lambda s : s[0];
4      elif how == 'values':
5          sort_function = lambda s : s[1];
6      else:
7          raise Exception("Invalid sort function")
8      return sorted(kwargs.items(), key=sort_function)
9
10
11
12 k = sort_pairs( 'keys', foo = 23, bar = 47)

```

```
13 print(k)
14 v = sort_pairs( 'values', foo = 23, bar = 47)
15 print(v)
```

Python Packages

Why Create package

As a module gets larger and larger it will be more and more difficult to maintain.

It might be easier if we split it up into multiple files and put those files inside a directory. A 'package' is just that. A bunch of Python modules that belong together and are placed in a directory hierarchy. In order to tell Python that you really mean these files to be a package one must add a file called **init.py** in each directory of the project. In the most simple case the file can be empty.

- Code reuse
- Separation of concerns
- Easier distribution

Create package

```
1 mymath/  
2     __init__.py  
3     calc.py  
4     ...  
5     internal_use.py
```

```
1 def add(x, y):  
2     return x+y
```

```
1 # empty
```

Internal usage

```
1 import calc
2 print(calc.add(7, 8)) # 15
3
4 from calc import add
5 print(add(3, 5))      # 8
```

```
1 cd examples/package
2 python 1/mymath/internal_use.py
```

use module in package - relative path

```
1 import sys
2 import os
3
4 path = os.path.join(os.path.dirname(os.path.dirname(os.path.abspath(__file__))), '1')
5 # print(path) # /home/gabor/work/slides/python-programming/examples/package/1
6 sys.path.insert(0, path)
7
8 import mymath.calc
9 print(mymath.calc.add(2, 5))
10
11 from mymath.calc import add
12 print(add(2, 3))

1 7
2 5
```

use package (does not work)

```
1 import sys
2 import os
3
4 sys.path.insert(0, os.path.join(
5     os.path.dirname(os.path.dirname(os.path.abspath(__file__))),
6     '1' ) )
7
8 import mymath
9 print(mymath.calc.add(4, 7))
```

```

1  Traceback (most recent call last):
2    File "use_project/proj1_2.py", line 9, in <module>
3      print(mymath.calc.add(4, 7))
4  AttributeError: module 'mymath' has no attribute 'calc'

```

If we import the main package name, it does not have access to the module inside.

package importing (and exporting) module

Put import (and thus re-export) in `init.py`

```

1  def add(x, y):
2      return x+y

1  import mymath.calc

```

use package (module) with import

Still works...

```

1  import sys
2  import os
3
4  path = os.path.join( os.path.dirname(os.path.dirname(os.path.abspath(__file__))), '2\
5  ' )
6  # print(path)
7  sys.path.insert(0, path)
8
9  import mymath.calc
10 print(mymath.calc.add(2, 5))  # 7
11
12 from mymath.calc import add
13 print(add(2, 3))             # 5

```

use package with import

Now we can import the module from the package and use that.

```

1  import sys
2  import os
3
4  sys.path.insert(0, os.path.join(
5      os.path.dirname(os.path.dirname(os.path.abspath(__file__))),
6      '2' ) )
7
8  import mymath
9  print(mymath.calc.add(4, 7))  # 11
10
11 from mymath import calc
12 print(calc.add(5, 9))        # 14

```

Creating an installable Python package

The directory layout of a package:

```

1  └─ mymath
2  |   └─ calc.py
3  |   └─ __init__.py
4  └─ setup.py

```

```

1  from setuptools import setup
2
3
4
5
6
7  setup(name='mymath',
8        version='0.1',
9        description='The best math library',
10       url='http://github.com/szabgab/mymath',
11       author='Foo Bar',
12       author_email='foo@bar.com',
13       license='MIT',
14       packages=['mymath'],
15       zip_safe=False,
16       )

```

Create tar.gz file

```
1 $ python setup.py sdist
```

- mymath.egg-info/
- dist/mymath-0.1.tar.gz

```
1 running sdist
2 running egg_info
3 creating mymath.egg-info
4 writing mymath.egg-info/PKG-INFO
5 writing top-level names to mymath.egg-info/top_level.txt
6 writing dependency_links to mymath.egg-info/dependency_links.txt
7 writing manifest file 'mymath.egg-info/SOURCES.txt'
8 reading manifest file 'mymath.egg-info/SOURCES.txt'
9 writing manifest file 'mymath.egg-info/SOURCES.txt'
10 warning: sdist: standard file not found: should have one of README, README.txt
11
12 creating mymath-0.1
13 creating mymath-0.1/mymath
14 creating mymath-0.1/mymath.egg-info
15 making hard links in mymath-0.1...
16 hard linking setup.py -> mymath-0.1
17 hard linking mymath/__init__.py -> mymath-0.1/mymath
18 hard linking mymath.egg-info/PKG-INFO -> mymath-0.1/mymath.egg-info
19 hard linking mymath.egg-info/SOURCES.txt -> mymath-0.1/mymath.egg-info
20 hard linking mymath.egg-info/dependency_links.txt -> mymath-0.1/mymath.egg-info
21 hard linking mymath.egg-info/not-zip-safe -> mymath-0.1/mymath.egg-info
22 hard linking mymath.egg-info/top_level.txt -> mymath-0.1/mymath.egg-info
23 Writing mymath-0.1/setup.cfg
24 creating dist
25 Creating tar archive
26 removing 'mymath-0.1' (and everything under it)
```

Install Package

```
1 $ pip install dist/mymath-0.1.tar.gz
```

```
1 $ easy_install --prefix ~/python/ dist/mymath-0.1.tar.gz
```

```
1 $ python setup.py install --prefix ~/python/
```

Upload to [PyPi](https://pypi.python.org/)²⁵⁶ or distribute to your users.

Dependencies

```
1 requires=[
2     'lawyerup',
3 ],
```

To list them

```
1 $ python setup.py --requires
```

In the setup.py file we only need to change the version number and we can release a new version of the package.

Add README file

```
1 .
2 └─ bin
3   └─ runmymath.bat
4   └─ runmymath.py
5 └─ MANIFEST.in
6 └─ mymath
7   └─ test
8       └─ __init__.py
9       └─ test_all.py
10      └─ test_calc.py
11 └─ README.rst
12 └─ setup.py
```

²⁵⁶<https://pypi.python.org/>

```
1 mymath
2 -----
3
4 Super awesome Python module to compute the sum of numbers.
5
6 To use:
7
8     import mymath
9     mymath.sum(1, 2, 3)
```

```
1 include README.rst
```

Add README file (setup.py)

In the setup.py add the following function:

```
1 def readme():
2     with open('README.rst') as f:
3         return f.read()
```

and in the setup() call include the following parameter:

```
1     long_description=readme(),
```

This will display the README file when called at

```
1 $ python setup.py --long-description
```

Include executables

```
1 root/
2   setup.py
3   README.rst
4   MANIFEST.in
5   bin/
6     runmymath.py
7     runmymath.bat
8   mymath/
9     __init__.py
10    calc.py
```

```
1 import mymath
2
3 def main():
4     print("running")
5
6 main()
```

```
1 echo "hi"
```

setup.py will need to get

```
1     scripts=['bin/runmymath.py', 'bin/runmymath.bat'],
```

Add tests

```
1     root/
2       setup.py
3       README.rst
4       MANIFEST.in
5       bin/
6         runmymath.py
7         runmymath.bat
8       mymath/
9         __init__.py
10      calc.py
11      test/
12        __init__.py
13        test_all.py
14        test_calc.py
```

```
1 #empty (needed for unittest discover)
```

```
1 python mymath/test/test_calc.py
```

```
2 python mymath/test/test_all.py
```

```
1 python -m unittest discover
```

Add tests calc

```
1 from os.path import dirname, abspath
2 import sys
3
4 sys.path.insert(0, dirname(dirname(dirname(abspath(__file__)))))
5 from mymath.calc import add
6 import unittest
7
8 class AddTest(unittest.TestCase):
9     def test_add(self):
10         self.assertEqual(add(2, 3), 5)
11         self.assertEqual(add(2, -2), 0)
12         #self.assertEqual(add(1, 1), 1)
13
14 if __name__ == '__main__':
15     unittest.main()
```

Add tests all

```
1 from os.path import dirname, abspath
2 import sys
3
4 sys.path.insert(0, dirname(dirname(dirname(abspath(__file__)))))
5 from mymath.calc import *
6 import unittest
7
8 class AllTest(unittest.TestCase):
9     def test_sum(self):
10         self.assertEqual(add(2, 3), 5)
11         #self.assertEqual(sum(1, 1), 2)
12         #self.assertEqual(div(6, 2), 3)
13
14 if __name__ == '__main__':
15     unittest.main()
```

setup.py

```
1  from setuptools import setup
2
3  def readme():
4      with open('README.rst') as f:
5          return f.read()
6
7  setup(name='mymath',
8        version='0.2',
9        description='The best math library',
10       url='http://github.com/szabgab/mymath',
11       author='Foo Bar',
12       author_email='foo@bar.com',
13       license='MIT',
14       packages=['mymath'],
15       zip_safe=False,
16       requires=[
17           'lawyerup',
18       ],
19       long_description=readme(),
20       scripts=['bin/runmymath.py', 'bin/runmymath.bat'],
21       )
```

Run tests and create package

```
1  python setup.py test
2  python setup.py sdist
```

Packaging applications (creating executable binaries)

- [py2exe](http://www.py2exe.org/)²⁵⁷ on Windows (discontinued)
- [Freeze](https://wiki.python.org/moin/Freeze)²⁵⁸ on Linux
- [py2app](https://py2app.readthedocs.io/en/latest/)²⁵⁹ on Mac
- [cx_Freeze](http://cx-freeze.sourceforge.net/)²⁶⁰ cross-platform
- [PyInstaller](http://www.pyinstaller.org/)²⁶¹ cross-platform
- [Auto Py To Exe](https://nitratine.net/blog/post/auto-py-to-exe/)²⁶²

²⁵⁷<http://www.py2exe.org/>

²⁵⁸<https://wiki.python.org/moin/Freeze>

²⁵⁹<https://py2app.readthedocs.io/en/latest/>

²⁶⁰<http://cx-freeze.sourceforge.net/>

²⁶¹<http://www.pyinstaller.org/>

²⁶²<https://nitratine.net/blog/post/auto-py-to-exe/>

Using PyInstaller

```
1 print("hello world")
```

```
1 pip install pyinstaller
2 pyinstaller myscript.py
3 pyinstaller --onefile hello_world.py
```

- See the results in dist/

Other PyInstaller examples

Use this to see where does the packaged version of our code look for modules:

```
1 import sys
2
3 print(sys.path)
```

Use this to see how to pass command line parameters to the packaged exe:

```
1 import sys
2
3 print(sys.argv)
```

Other

```
1 pyinstaller --onefile --windowed myscript.py
```

Py2app for Mac

```
1 pip install py2app
2 py2applet examples/basics/hello.py
```

Exercise: package

- Go to [PyPi](https://pypi.org/)²⁶³, find some interesting module and install it in a non-standard location (or in a virtualenv)
 - Check if it was installed (try to import it in a python script).
 - Take one of the previously created modules, and create a package for it.
 - Install this new package in a non-standard location.
 - Check if it works from some other place in your file-system.
-
- Take the mymath package, add another method, add tests and create the distubtable zip file.

Exercise: create executable

- Go over some of the examples in the course and package that.
- Package a script using some of your favorite modules.

²⁶³<https://pypi.org/>

Ctypes

ctypes - hello

```
1  #include <stdio.h>
2
3  char * echo(char * what)
4  {
5      return what;
6  }
7
8  int add_int(int a, int b)
9  {
10     int sum = a+b;
11     return sum;
12 }
13
14 int add_int(int a, int b)
15 {
16     int sum = a+b;
17     return sum;
18 }
19
20
21 int main(void)
22 {
23     printf("hello\n");
24     printf("%d\n", add_int(2, 3));
25     printf("%s\n", echo("Foo"));
26     return 0;
27 }
```

```
1  gcc -o hello hello.c
2  gcc -o hello.so -shared -fPIC hello.c
```

```
1  from ctypes import cdll
2  from ctypes import c_char_p
3
4  hello_lib = cdll.LoadLibrary("hello.so")
5
6  print(hello_lib.add_int(4, 5))          # 9
7
8  print(hello_lib.echo('Hello World'))    # 153977204
9
10
11 hello_lib.echo.restype = c_char_p
12 print(hello_lib.echo('Hello World'))    # Hello World
```

concat

```
1  #include <stdio.h>
2  #include <string.h>
3  #include <stdlib.h>
4
5  int len(char * s)
6  {
7      return strlen(s);
8  }
9
10 char * concat(char * a, char * b)
11 {
12     char * res;
13     int leng = strlen(a) + strlen(b);
14     res = (char *)malloc(leng);
15     strcpy (res, a);
16     strcat (res, b);
17     return res;
18 }
19
20
21 int main(void)
22 {
23     printf("concat\n");
24     printf("%d\n", len("abc"));
25     printf("%d\n", len(""));
26     printf("%d\n", len("xxxxxxxxxx"));
27     printf("%s\n", concat("Foo1", "Bar"));
```

```
28     return 0;
29 }

1  from ctypes import cdll
2  from ctypes import c_char_p
3
4  more_lib = cdll.LoadLibrary("more.so")
5
6  print(more_lib.len("abcd"))      # 4
7  print(more_lib.len(""))         # 0
8  print(more_lib.len("x" * 123))  # 123
9
10
11 more_lib.concat.restype = c_char_p
12 print(more_lib.concat("abc", "def"))
```

Advanced OOP

Class count instances

```
1 class Person:
2     count = 0
3     def __init__(self, name):
4         self.name = name
5         #Person.count += 1
6         #self.count += 1
7         self.count = self.count + 1
8
9
10 print(Person.count)
11 joe = Person("Joe")
12 print(Person.count)
13 print(joe.count)
14
15 jane = Person("Jane")
16 print(Person.count)
17 print(jane.count)
```

```
1 0
2 0
3 1
4 0
5 1
```

Class Attributes

- Class attributes can be created inside a class.
- Assign to class attribute and fetch from it
- Class attributes can be also created from the outside.

```
1 class Person:
2     name = 'Joseph'
3
4 print(Person.name)    # Joseph
5
6 Person.name = 'Joe'
7 print(Person.name)    # Joe
8
9 Person.email = 'joe@foobar.com'
10 print(Person.email)  # joe@foobar.com
```

Class Attributes in Instances

```
1 class Person:
2     name = 'Joe'
3
4 # Class Attributes are inherited by object instances when accessing them.
5 x = Person()
6 print(x.name)        # Joe
7 y = Person()
8 print(y.name)        # Joe
9
10 # Changes to class attribute are reflected in existing instances as well
11 Person.name = 'Bar'
12 print(Person.name)   # Bar
13 print(x.name)        # Bar
14
15 # Setting the attribute via the instance will create an instance attribute that
16 # shadows the class attribute
17 x.name = 'Joseph'
18 print(x.name)        # Joseph
19 print(Person.name)   # Bar
20 # Nor does it impact the instance attribute of other instances:
21 print(y.name)        # Bar
22
23 # Both instance and class have a dictionary containing its members:
24 print(x.__dict__)     # {'name': 'Joseph'}
25 print(y.__dict__)     # {}
26 print(Person.__dict__) # {..., 'name': 'Bar'}
```

Attributes with method access

- Use a method (show) to access it.

```
1 class Person():
2     name = 'Joe'
3     print(f'Hello {name}')
4
5     def show(self):
6         print(Person.name)
7
8 x = Person()           # Hello Joe
9 x.show()               # Joe
10 print(x.name)         # Joe
11 print(Person.name)    # Joe
12
13 Person.name = 'Jane'
14 print(x.name)         # Jane
15 print(Person.name)    # Jane
16 x.show()              # Jane
17
18 x.name = 'Hilda'      # creating and setting the instance attribute
19 print(x.name)         # Hilda
20 print(Person.name)    # Jane
21
22 x.show()              # Jane
```

Instance Attribute

The attributes of the instance object can be set via 'self' from within the class.

```
1 class Person():
2     name = 'Joseph'
3
4     def __init__(self, given_name):
5         self.name = given_name
6
7     def show_class(self):
8         return Person.name
9
```

```
10     def show_instance(self):
11         return self.name
12
13 print(Person.name)          # Joseph
14
15 Person.name = 'Classy'
16 print(Person.name)         # Classy
17 # print(Person.show_class()) # TypeError: show_class() missing 1 required positional\
18     argument: 'self'
19
20 x = Person('Joe')
21 print(x.name)              # Joe
22 print(Person.name)         # Classy
23 print(x.show_class())      # Classy
24 print(x.show_instance())   # Joe
25
26 Person.name = 'General'
27 print(x.name)              # Joe
28 print(Person.name)         # General
29 print(x.show_class())      # General
30 print(x.show_instance())   # Joe
31
32 x.name = 'Zorg'            # changing the instance attribute
33 print(x.name)              # Zorg
34 print(Person.name)         # General
35 print(x.show_class())      # General
36 print(x.show_instance())   # Zorg
```

Methods are class attributes

In this example we are going to replace the method in the class by a newly created function. (monkey patching)

```
1  class Person():
2      def __init__(self, name):
3          self.name = name
4
5      def show(self):
6          return self.name
7
8  y = Person('Jane')
9  print(y.show())          # Jane
10
11 def new_show(some_instance):
12     print("Hello " + some_instance.name)
13     return some_instance
14
15 Person.show = new_show
16 y.show()                 # Hello Jane
```

Monkey patching

```
1  class Person():
2      def __init__(self, name):
3          self.name = name
4
5      def show(self):
6          return self.name
7
8  x = Person('Joe')
9  print(x.show())          # Joe
10
11 def patch(class_name):
12     temp = class_name.show
13     def debug(*args, **kwargs):
14         print("in debug")
15         return temp(*args, **kwargs)
16     class_name.show = debug
17
18 patch(Person)
19
20 print(x.show())
21     # in debug
22     # Joe
```

Classes: instance method

Regular functions (methods) defined in a class are “instance methods”. They can only be called on “instance objects” and not on the “class object” as see in the 3rd example.

The attributes created with “self.something = value” belong to the individual instance object.

```
1 class Date:
2     def __init__(self, Year, Month, Day):
3         self.year  = Year
4         self.month = Month
5         self.day   = Day
6
7     def __str__(self):
8         return 'Date({}, {}, {})'.format(self.year, self.month, self.day)
9
10    def set_date(self, y, m, d):
11        self.year = y
12        self.month = m
13        self.day = d
```

```
1 from mydate import Date
2
3 d = Date(2013, 11, 22)
4 print(d)
5
6 # We can call it on the instance
7 d.set_date(2014, 1, 27)
8 print(d)
9
10 # If we call it on the class, we need to pass an instance.
11 # Not what you would normally do.
12 Date.set_date(d, 2000, 2, 1)
13 print(d)
14
```

```

15
16 # If we call it on the class, we get an error
17 Date.set_date(1999, 2, 1)

```

set_date is an instance method. We cannot properly call it on a class.

```

1 Date(2013, 11, 22)
2 Date(2014, 1, 27)
3 Date(2000, 2, 1)
4 Traceback (most recent call last):
5   File "run.py", line 17, in <module>
6     Date.set_date(1999, 2, 1)
7   TypeError: set_date() missing 1 required positional argument: 'd'

```

Class methods and class attributes

“total” is an attribute that belongs to the class. We can access it using Date.total. We can create a @classmethod to access it, but actually we can access it from the outside even without the class method, just using the “class object”

```

1 class Date:
2     total = 0
3
4     def __init__(self, Year, Month, Day):
5         self.year = Year
6         self.month = Month
7         self.day = Day
8         Date.total += 1
9
10    def __str__(self):
11        return 'Date({}, {}, {})'.format(self.year, self.month, self.day)
12
13    def set_date(self, y, m, d):
14        self.year = y
15        self.month = m
16        self.day = d
17
18    @classmethod
19    def get_total(class_object):
20        print(class_object)
21        return class_object.total

```

```

1  from mydate import Date
2
3  d1 = Date(2013, 11, 22)
4  print(d1)
5  print(Date.get_total())
6  print(Date.total)
7  print(' ')
8
9  d2 = Date(2014, 11, 22)
10 print(d2)
11 print(Date.get_total())
12 print(Date.total)
13 print(' ')
14
15 d1.total = 42
16 print(d1.total)
17 print(d2.total)
18 print(Date.get_total())
19 print(Date.total)

```

```

1  Date(2013, 11, 22)
2  <class 'mydate.Date'>
3  1
4  1
5
6  Date(2014, 11, 22)
7  <class 'mydate.Date'>
8  2
9  2
10
11 42
12 2
13 <class 'mydate.Date'>
14 2
15 2

```

Classes: constructor

- The “class” keyword creates a “class object”. The default constructor of these classes are their own names.
- The actual code is implemented in the `__new__` method of the object.
- Calling the constructor will create an “instance object”.

Class methods - alternative constructor

Class methods are used as Factory methods, they are usually good for alternative constructors. In order to be able to use a method as a class-method

(Calling `Date.method(...)` one needs to mark the method with the `@classmethod` decorator)

```
1 class Date:
2     def __init__(self, Year, Month, Day):
3         self.year = Year
4         self.month = Month
5         self.day = Day
6
7     def __str__(self):
8         return 'Date({}, {}, {})'.format(self.year, self.month, self.day)
9
10    def set_date(self, y, m, d):
11        self.year = y
12        self.month = m
13        self.day = d
14
15    @classmethod
16    def from_str(class_object, date_str):
17        '''Call as
18            d = Date.from_str('2013-12-30')
19        '''
20        print(class_object)
21        year, month, day = map(int, date_str.split('-'))
22        return class_object(year, month, day)
```

```
1 from mydate import Date
2
3 d = Date(2013, 11, 22)
4 print(d)
5
6 d.set_date(2014, 1, 27)
7 print(d)
8
9 print('')
10 dd = Date.from_str('2013-10-20')
11 print(dd)
12
```

```
13 print('')
14 z = d.from_str('2012-10-20')
15 print(d)
16 print(z)
```

```
1 Date(2013, 11, 22)
2 Date(2014, 1, 27)
3
4 <class 'mydate.Date'>
5 Date(2013, 10, 20)
6
7 <class 'mydate.Date'>
8 Date(2014, 1, 27)
9 Date(2012, 10, 20)
```

Abstract Base Class

- Create a class object that cannot be used to create an instance object. (It must be subclassed)
- The subclass must implement certain methods required by the base-class.

```
1 class NotImplementedError(Exception):
2     pass
3
4 class Base():
5     def foo(self):
6         raise NotImplementedError()
7
8     def bar(self):
9         raise NotImplementedError()
10
11 class Real(Base):
12     def foo(self):
13         print('foo in Real')
14     def bar(self):
15         print('bar in Real')
16     def other(self):
17         pass
18
19 class Fake(Base):
20     def foo(self):
```

```

21         print('foo in Fake')
22
23     r = Real()
24     r.foo()
25     r.bar()
26     f = Fake()
27     f.foo()
28     f.bar()

1  foo in Real
2  bar in Real
3  foo in Fake
4  Traceback (most recent call last):
5      File "no_abc.py", line 28, in <module>
6          f.bar()      # NotImplementedError
7      File "no_abc.py", line 9, in bar
8          raise NotImplementedError()
9  __main__.NotImplementedError

```

Abstract Base Class with abc

- [abc](https://docs.python.org/library/abc.html)²⁶⁶

```

1  from abc import ABC, abstractmethod
2
3  class Base(ABC):
4      def __init__(self, name):
5          self.name = name
6
7      @abstractmethod
8      def foo(self):
9          pass
10
11     @abstractmethod
12     def bar(self):
13         pass

```

ABC working example

²⁶⁶<https://docs.python.org/library/abc.html>

```
1  from with_abc3 import Base
2
3  class Real(Base):
4      def foo(self):
5          print('foo in Real')
6
7      def bar(self):
8          print('bar in Real')
9
10     def other(self):
11         pass
12
13 r = Real('Jane')
14 print(r.name)      # Jane
```

```
1  Jane
```

ABC - cannot instantiate the base-class

```
1  from with_abc3 import Base
2
3  b = Base('Boss')
```

```
1  Traceback (most recent call last):
2      File "with_abc3_base.py", line 3, in <module>
3          b = Base('Boss')
4  TypeError: Can't instantiate abstract class Base with abstract methods bar, foo
```

ABC - must implement methods

```
1  from with_abc3 import Base
2
3  class Fake(Base):
4      def foo(self):
5          print('foo in Fake')
6
7  f = Fake('Joe')
```

```
1  Traceback (most recent call last):
2    File "with_abc3_fake.py", line 7, in <module>
3        f = Fake('Joe')
4  TypeError: Can't instantiate abstract class Fake with abstract methods bar
```

Use Python @property to fix bad interface (the bad interface)

When we created the class the first time we wanted to have a field representing the age of a person. (For simplicity of the example we only store the years.)

```
1  class Person():
2      def __init__(self, age):
3          self.age = age
4
5  p = Person(19)
6  print(p.age)          # 19
7
8  p.age = p.age + 1
9  print(p.age)          # 20
```

Only after releasing it to the public have we noticed the problem. Age changes.

We would have been better off storing birthdate and if necessary calculating the age.

How can we fix this?

Use Python @property to fix bad interface (first attempt)

This might have been a good solution, but now we cannot use this as a “fix” as this would change the public interface from `p.age` to `p.age()`

```

1  from datetime import datetime
2  class Person():
3      def __init__(self, years):
4          self.set_birthyear(years)
5
6      def get_birthyear(self):
7          return datetime.now().year - self._birthyear
8
9      def set_birthyear(self, years):
10         self._birthyear = datetime.now().year - years
11
12     def age(self, years=None):
13         if (years):
14             self.set_birthyear(years)
15         else:
16             return self.get_birthyear()
17
18
19
20 p = Person(19)
21 print(p.age())          # 19
22
23 p.age(p.age() + 1)
24 print(p.age())          # 20

```

Use Python @property to fix bad API

```

1  property(fget=None, fset=None, fdel=None, doc=None)

1  from datetime import datetime
2  class Person():
3      def __init__(self, years):
4          self.age = years
5
6      def get_birthyear(self):
7          return datetime.now().year - self.birthyear
8
9      def set_birthyear(self, years):
10         self.birthyear = datetime.now().year - years
11
12     age = property(get_birthyear, set_birthyear)

```

```

13
14 p = Person(19)
15 print(p.age)          # 19
16
17 p.age = p.age + 1
18 print(p.age)          # 20
19
20 p.birthyear = 1992
21 print(p.age)          # 28
22     # warning: this will be different if you run the example in a year different from\
23     2020 :)

```

Use Python @property decorator to fix bad API

```

1  from datetime import datetime
2  class Person():
3      def __init__(self, years):
4          self.age = years
5
6      # creates "getter"
7      @property
8      def age(self):
9          return datetime.now().year - self.birthyear
10
11     # creates "setter"
12     @age.setter
13     def age(self, years):
14         self.birthyear = datetime.now().year - years
15
16 p = Person(19)
17 print(p.age)          # 19
18
19 p.age = p.age + 1
20 print(p.age)          # 20
21
22
23 p.birthyear = 1992
24 print(p.age)          # 28
25     # warning: this will be different if you run the example in a year different from\
26     2020 :)

```

Use Python @property for value validation

```
1  from datetime import datetime
2  class Person():
3      def __init__(self, years):
4          self.age = years
5
6      @property
7      def age(self):
8          return datetime.now().year - self.birthyear
9
10     @age.setter
11     def age(self, years):
12         if years < 0:
13             raise ValueError("Age cannot be negative")
14         self.birthyear = datetime.now().year - years
```

```
1  from person5 import Person
2
3  p = Person(19)
4  print(p.age)          # 19
5
6  p.age = p.age + 1
7  print(p.age)          # 20
8
9  p.birthyear = 1992
10 print(p.age)           # 28
11     # warning: this will be different if you run the example in a year different from\
12     2020 :)
```

class and static methods

Static methods are used when no “class-object” and no “instance-object” is required. They are called on the class-object, but they don’t receive it as a parameter.

They might be better off placed in a module, like the `other_method`.

```
1 def other_method(val):
2     print(f"other_method: {val}")
3
4 class Date(object):
5     def __init__(self, Year, Month, Day):
6         self.year = Year
7         self.month = Month
8         self.day = Day
9
10    def __str__(self):
11        return 'Date({}, {}, {})'.format(self.year, self.month, self.day)
12
13    @classmethod
14    def from_str(class_object, date_str):
15        '''Call as
16           d = Date.from_str('2013-12-30')
17           '''
18        print(f"from_str: {class_object}")
19        year, month, day = map(int, date_str.split('-'))
20
21        other_method(43)
22
23        if class_object.is_valid_date(year, month, day):
24            return class_object(year, month, day)
25        else:
26            raise Exception("Invalid date")
27
28    @staticmethod
29    def is_valid_date(year, month, day):
30        if 0 <= year <= 3000 and 1 <= month <= 12 and 1 <= day <= 31:
31            return True
32        else:
33            return False
```

```

1  import mydate
2
3  dd = mydate.Date.from_str('2013-10-20')
4  print(dd)
5
6  print('')
7  print(mydate.Date.is_valid_date(2013, 10, 20))
8  print(mydate.Date.is_valid_date(2013, 10, 32))
9  print('')
10
11 x = mydate.Date.from_str('2013-10-32')

```

```

1  from_str: <class 'mydate.Date'>
2  other_method: 43
3  Date(2013, 10, 20)
4
5  True
6  False
7
8  from_str: <class 'mydate.Date'>
9  other_method: 43
10 Traceback (most recent call last):
11   File "run.py", line 11, in <module>
12     x = mydate.Date.from_str('2013-10-32')

15     raise Exception("Invalid date")
16 Exception: Invalid date

```

Destructor: del

```

1  class Person:
2      def __init__(self):
3          print('__init__')
4      def __del__(self):
5          print('__del__')
6
7  def main():
8      a = Person()
9      print('in main - after')
10

```

```

11 main()
12 print('after main')

```

```

1  __init__
2  in main - after
3  __del__
4  after main

```

Destructor delayed

Because the object has a reference to itself. (Python uses both reference count and garbage collection.)

```

1  class Person:
2      def __init__(self, name):
3          self.name = name
4          print(f'__init__ {name}')
5
6      def __del__(self):
7          print(f'__del__ {self.name}')
8
9  def main():
10     a = Person('A')
11     b = Person('B')
12     a.partner = a
13     print('in main - after')
14
15 main()
16 print('after main')

```

```

1  __init__ A
2  __init__ B
3  in main - after
4  __del__ B
5  after main
6  __del__ A

```

Destructor delayed for both

Because the instances reference each other

```

1  class Person:
2      def __init__(self, name):
3          self.name = name
4          print(f'__init__ for {self.name}')
5      def __del__(self):
6          print(f'__del__ for {self.name}')
7
8  def main():
9      a = Person('Joe')
10     b = Person('Jane')
11     a.partner = b
12     b.partner = a
13     print('in main - after')
14
15 main()
16 print('after main')

```

```

1  __init__ for Joe
2  __init__ for Jane
3  in main - after
4  after main
5  __del__ for Joe
6  __del__ for Jane

```

Operator overloading

```

1  import copy
2
3  class Rect:
4      def __init__(self, w, h):
5          self.width = w
6          self.height = h
7
8      def __str__(self):
9          return 'Rect[{}, {}]'.format(self.width, self.height)
10
11     def __mul__(self, other):
12         o = int(other)
13         new = copy.deepcopy(self)
14         new.height *= o
15         return new

```

```

1  import shapes
2
3  r = shapes.Rect(10, 20)
4  print(r)
5  print(r * 3)
6  print(r)
7
8  print(4 * r)

```

```

1  Rect[10, 20]
2  Rect[10, 60]
3  Rect[10, 20]
4  Traceback (most recent call last):
5    File "rect.py", line 8, in <module>
6      print(4 * r)
7  TypeError: unsupported operand type(s) for *: 'int' and 'Rect'

```

In order to make the multiplication work in the other direction, one needs to implement the **rmul** method.

Operator overloading methods

```

1  *      __mul__, __rmul__
2  +      __add__, __radd__
3  +=     __iadd__
4  <      __lt__
5  <=     __le__
6  ...

```

- [see all of them in datamodel](#)²⁶⁹

Exercise: rectangular

Take the Rect class in the shapes module. Implement **rmul**, but in that case multiply the width of the rectangular.

Implement the addition of two rectangulars. I think this should be defined only if one of the sides is the same,

²⁶⁹<https://docs.python.org/reference/datamodel.html>

but if you have an idea how to add two rectangulars of different sides, then go ahead, implement that.

Also implement all the comparison operators when comparing two rectangulars, compare the area of the two. (like less-than)

Do you need to implement all of them?

Exercise: SNMP numbers

- SNMP numbers are strings consisting a series of integers separated by dots: 1.5.2, 3.7.11.2
- Create a class that can hold such an snmp number. Make sure we can compare them with less-than (the comparison is pair-wise for each number until we find two numbers that are different. If one SNMP number is the prefix of the other then the shorter is “smaller”).
- Add a class-method, that can tell us how many SNMP numbers have been created.
- Write a separate file to add unit-tests

Exercise: Implement a Gene inheritance model combining DNA

- A class representing a person. It has an attribute called “genes” which is string of letters. Each character is a gene.
- Implement the + operator on genes that will create a new “Person” and for the gene will select one randomly from each parent.

```
1 a = Person('ABC')
2 b = Person('DEF')
3
4 c = a + b
5 print(c.gene) # ABF
```

Exercise: imaginary numbers - complex numbers

Create a class that will represent imaginary numbers ($x, y*i$) and has methods to add and multiply two imaginary numbers.

```
1 The math:
2
3 z1 = (x1 + y1*i)
4 z2 = (x2 + y2*i)
5 z1+z2 = (x1 + x2 + (y1 + y2)*i)
6
7 z1*z2 = x1*y1 + x2*y2*i*i + x1*y2*i + x2*y1*i
```

Add operator overloading so we can really write code like:

```
1 z1 = Z(2, 3)
2 z2 = Z(4, 7)
3
4 zz = z1*z2
```

- See [cmath](#)²⁷⁰

```
1 z = complex(2, 3)
2 print(z)
3 print(z.real)
4 print(z.imag)
5
6 imag = (-1) ** 0.5
7 print(imag)
8
9 i = complex(0, 1)
10 print(i)
11 print(i ** 2)
```

```
1 (2+3j)
2 2.0
3 3.0
4 (6.123233995736766e-17+1j)
5 1j
6 (-1+0j)
```

Solution: Rectangular

²⁷⁰<https://docs.python.org/library/cmath.html>

```
1  import copy
2  import shapes
3
4  class Rectangular(shapes.Rect):
5
6      def __rmul__(self, other):
7          o = int(other)
8          new = copy.deepcopy(self)
9          new.width *= o
10         return new
11
12     def area(self):
13         return self.width * self.height
14
15     def __eq__(self, other):
16         return self.area() == other.area()
17
18     def __add__(self, other):
19         new = copy.deepcopy(self)
20         if self.width == other.width:
21             new.height += other.height
22         elif self.height == other.height:
23             new.width += other.width
24         else:
25             raise Exception('None of the sides are equal')
26         return new

```

```
1  import shape2
2  import unittest
3
4  class TestRect(unittest.TestCase):
5
6      def assertEqualSides(self, left, right):
7          if isinstance(right, tuple):
8              right = shape2.Rectangular(*right)
9
10         if left.width != right.width:
11             raise AssertionError('widths are different')
12         if left.height != right.height:
13             raise AssertionError('heights are different')
14
15     def setUp(self):
```

```
16         self.a = shape2.Rectangular(4, 10)
17         self.b = shape2.Rectangular(2, 20)
18         self.c = shape2.Rectangular(1, 30)
19         self.d = shape2.Rectangular(4, 10)
20
21     def test_sanity(self):
22         self.assertEqual(self.a, self.a)
23         self.assertEqual(self.a, self.d)
24         try:
25             self.assertEqual(self.a, self.b)
26         except AssertionError as e:
27             self.assertEqual(e.args[0], 'widths are different')
28
29         try:
30             self.assertEqual(self.a, shape2.Rectangular(4, 20))
31         except AssertionError as e:
32             self.assertEqual(e.args[0], 'heights are different')
33
34         self.assertEqual(self.a, (4, 10))
35
36     def test_str(self):
37         self.assertEqual(str(self.a), 'Rect[4, 10]')
38         self.assertEqual(str(self.b), 'Rect[2, 20]')
39         self.assertEqual(str(self.c), 'Rect[1, 30]')
40
41     def test_mul(self):
42         self.assertEqual(str(self.a * 3), 'Rect[4, 30]')
43         self.assertEqual(str(self.b * 7), 'Rect[2, 140]')
44
45     def test_rmul(self):
46         self.assertEqual(str(3 * self.a), 'Rect[12, 10]')
47         self.assertEqualSides(3 * self.a, (12, 10))
48
49     def test_area(self):
50         self.assertEqual(self.a.area(), 40)
51         self.assertEqual(self.b.area(), 40)
52         self.assertEqual(self.c.area(), 30)
53
54     def test_equal(self):

65     unittest.main()
```

Solution: Implement a Gene inheritance model combining DNA

```
1  import random
2
3  class Person(object):
4      def __init__(self, DNA):
5          self.DNA = DNA
6
7      def gene(self):
8          return list(self.DNA)
9
10     def print_genes(self):
11         print(list(self.DNA))
12
13     def __add__(self, other):
14         DNA_father = self.gene()
15         DNA_mother = other.gene()
16         if len(DNA_father) != len(DNA_mother):
17             raise Exception("Incompatible couple")
18
19         DNA_childPossible_sequence = DNA_father + DNA_mother
20         DNA_child = ""
21         for i in range(len(self.gene())):
22             DNA_child += random.choice([DNA_father[i], DNA_mother[i]])
23
24         return Person(DNA_child)
25
26
27 a = Person("ABCD")
28 b = Person("1234")
29 c = a + b
30 print(c.DNA)
```

Instance counter

```
1  class Bike:
2      count = 0
3      def __init__(self):
4          Bike.count += 1
5
6      def __del__(self):
7          Bike.count -= 1
8
9  def bike_trip():
10     print(Bike.count)    # 0
11     a = Bike()
12     print(Bike.count)    # 1
13     b = Bike()
14     print(Bike.count)    # 2
15     c = Bike()
16     print(Bike.count)    # 3
17     b = None
18     print(Bike.count)    # 2
19
20
21 bike_trip()
22 print(Bike.count)        # 0
```

2to3

Convertig from Python 2 to Python 3

from future import ...

division

```
1 print 3/2    # 1
```

```
1 from __future__ import division
2
3 print 3/2    # 1.5
```

print in Python 2

```
1 fname = 'Foo'
2 lname = 'Bar'
3 print("Name: %s %s" % (fname, lname))
4 print("Name: {} {}".format(fname, lname))
5 print(fname, lname)
6 print fname, lname
```

```
1 Name: Foo Bar
2 Name: Foo Bar
3 ('Foo', 'Bar')
4 Foo Bar
```

print in Python 3

print now requires print()

```
1  from __future__ import print_function
2
3  fname = 'Foo'
4  lname = 'Bar'
5  print("Name: %s %s" % (fname, lname))
6  print("Name: {} {}".format(fname, lname))
7  print(fname, lname)
```

```
1  Name: Foo Bar
2  Name: Foo Bar
3  Foo Bar
```

input and raw_input

`raw_input()` was renamed to `input()`

In Python 2 `raw_input()` returned the raw string. `input()`, on the other hand ran `eval(raw_input())` which meant it tried to execute the input string as a piece of Python code. This was dangerous and was not really used.

In Python 3 `raw_input()` is gone. `input()` behaves as the old `raw_input()` returning the raw string. If you would like to get the old, and dangerous, behavior of `input()` you can call `eval(input())`.

Code that works on both 2 and 3

```
1  import platform
2
3  def my_input(text):
4      if platform.python_version_tuple()[0] == 3:
5          return input(text)
6      else:
7          return raw_input(text)
```

Compare different types

```

1 x = 3
2 y = '3'
3
4                                     # Python 2      Python 3
5 print( x > y )                      # False        TypeError: unorderable types: int() > str()
6 print( x < y )                      # True         TypeError: unorderable types: int() < str()
7 print( x == y )                    # False         False

```

Octal numbers

Octal numbers in 2.x was 011 in 3.x is: 0o11

Design Patterns

What are Design Patterns?

Not all the Design Patterns discussed for Java or C++ are interesting, relevant or even needed in Python.

Design Patterns are formal descriptions of how people do things, and not how you should do things. The formal description makes it easy to talk about them.

Some of the DPs exist to overcome problems in that specific language. Other DPs are more general, solving classes of problems that are generic.

Don't replace built-in objects

```
1 import sys
2
3 print = 'hello'
4 sys.stdout.write(print)
5 sys.stdout.write('\n')
```

```
1 pip install flake8-builtins
2 flake8 --ignore= replace_print.py
3
4 replace_print.py:3:1: A001 "print" is a python builtin and is being shadowed, consider renaming the variable
```

Facade - simple interface to complex system

Facade, a structural design pattern. - Provide a simple interface (maybe a single class with few methods) to some complex system behind it.

This gives flexibility for the implementation of the complex system while users gain simplicity in using

it in certain subsets of operations.

```
1 os.path.basename, os.path.dirname are faced for os.path.split + indexing in the list
2 os.path.basename = os.path.split()[-1]
3 os.path.split = split with os.sep
4 os.path.join(names) = os.sep.join(names)
5 os.path.isdir(path) = stat.S_ISDIR(os.stat(path))
```

- [\[\]](http://docs.python.org/library/os.path.html)(<http://docs.python.org/library/os.path.html>)
- [\[\]](http://docs.python.org/library/os.html)(<http://docs.python.org/library/os.html>)
- [\[\]](http://docs.python.org/library/stat.html)(<http://docs.python.org/library/stat.html>)

Monkey Patching

```
1 import real_class
2 class faker(object): pass
3 fake = faker
4 real_class.time = fake
5 fake.sleep =
6 fake.time =
```

- handy in emergencies
- easily abused for NON-emergencies - gives dynamic languages a bad name
- subtle hidden “communication” via secret obscure pathways (explicit is better)

```
1 class Monkey:
2
3     def __init__(self, count):
4         self.bananas = count
5
6     def is_hungry(self):
7         hungry = True
8         if hungry:
9             self.eat()
10
11     def eat(self):
12         self.bananas -= 1
13
```

```

14
15 m = Monkey(10)
16 print(m.bananas)           # 10
17 print(m.is_hungry())       # None
18 print(m.bananas)           # 9
19
20 Monkey.eat = lambda self: True
21
22 om = Monkey(10)
23 print(om.bananas)           # 10
24 print(om.is_hungry())       # None
25 print(om.bananas)           # 10

```

Creation DPs “Just One”

we want just one instance to exist

- Singleton - subclassing can never be really smooth
- Use a module instead of a class (no inheritance, no special methods)
- make just one instance (self discipline, no enforcement), need to decide to “when” (in which part of the code) to make it
- monostate (borg)

Singleton

```

1  class Singleton(object):
2      def __new__(cls, *a, **kw):
3          if not hasattr(cls, '_inst'):
4              cls._inst = super(Singleton, cls).__new__(cls, *a, **kw)
5          return cls._inst

```

the problem

```

1  class Foo(Singleton): pass
2  class Bar(Foo): pass
3  f = Foo()
4  b = Bar()
5  # what class is b now? is that a Bar or a Foo instance?

```

Monostate (Borg)

- [Monostate Pattern](#)²⁷⁸

```
1 class Monostate(object):
2     _shared_state = {}
3     def __new__(cls, *a, **kw):
4         obj = super(Monostate, cls).__new__(*a, **kw)
5         obj.__dict__ = _shared_state
6         return obj
7
8 class Foo(Monostate) pass
9 class Bar(Foo) pass
10 f = Foo()
11 b = Bar()
```

Better than singleton, data overriding to the rescue:

But what if two calls to the constructor provide different initial data?

Dispatch table

```
1 calls = []
2 calls.append( lambda x: x+1 )
3 calls.append( lambda x: x*2 )
4
5 others = [
6     lambda x: x-1,
7     lambda x: 0
8 ]
9
10 def do_something( call_list ):
11     for c in call_list:
12         print(c(3))
13
14
15 do_something( calls )
16 do_something( others )
```

²⁷⁸<http://c2.com/cgi/wiki?MonostatePattern>

Parallel

Types of Problems

- CPU intensive application - use more of the cores to reduce the wallclock time.
- IO intensive applications - don't waste the CPU and wallclock time while waiting for the IO process.
- Interactive applications - make sure they are responsive during long operations.

Types of solutions

- Number of processes (forking on Unix or spawning)
- Number of threads (Single threaded vs Multi-threaded)
- Asynchronous, non-blocking or synchronous vs blocking (aka "normal") Cooperative Multi-tasking

How many parallels to use?

* First of all, I call them "parallels" as this applies to forks, threads, spawns, and even to async code.

- Overhead of creating new parallel.
- Overhead of communication (sending job input to parallel, receiving results).
- Total number of items to process.
- Time it takes to process an item.
- Distribution of processing times. (e.g. one long and many short jobs.)
- Number of cores (CPUs).

Dividing jobs

- N items to process
- K in parallel
- Divide the items in K groups of size $\text{int}(N/K)$ and $\text{int}(N/K)+1$.
- Create K parallels with one item each. When it is done, give it another item.
- Create K parallels with one item each. When done let it stop and create a new parallel.

Performance Monitoring

- Linux, OSX: `htop`
- Windows: Performance Monitor

Threads

Python Threading docs

- [threading](#)²⁷⁹
- [Real Python](#)²⁸⁰
- [Wikibooks](#)²⁸¹

Threaded counters

```
1  import threading
2  import sys
3
4  class ThreadedCount(threading.Thread):
5      def run(self):
6          for cnt in range(6):
7              print(f"{cnt} {threading.current_thread().name}")
8          return
9
10 a = ThreadedCount()
11 b = ThreadedCount()
12 c = ThreadedCount()
13
14 a.start()
15 b.start()
16 c.start()
17 print('main - Running {} threads'.format(threading.active_count()))
18
19 a.join()
20 b.join()
21 c.join()
22 print("main - thread is done")
```

²⁷⁹<https://docs.python.org/library/threading.html>

²⁸⁰<https://realpython.com/intro-to-python-threading/>

²⁸¹https://en.wikibooks.org/wiki/Python_Programming/Threading

```
1 0 Thread-1
2 1 Thread-1
3 0 Thread-2
4 2 Thread-1
5 1 Thread-2
6 0 Thread-3
7 3 Thread-1
8 2 Thread-2
9 main - Running 4 threads
10 3 Thread-2
11 1 Thread-3
12 4 Thread-2
13 2 Thread-3
14 5 Thread-2
15 3 Thread-3
16 4 Thread-1
17 4 Thread-3
18 5 Thread-1
19 5 Thread-3
20 main - thread is done
```

Simple threaded counters

```
1 import threading
2 import sys
3
4 class ThreadedCount(threading.Thread):
5     def run(self):
6         thread = threading.current_thread()
7         print('{} - start'.format(thread.name))
8         for c in range(10):
9             print('{} - count {}'.format(thread.name, c))
10        print('{} - end'.format(thread.name))
11        return
12
13 a = ThreadedCount()
14 b = ThreadedCount()
15 c = ThreadedCount()
16 a.start()
17 b.start()
18 c.start()
19
```

```
20 print('main - running {} threads'.format(threading.active_count()))
21
22 a.join()
23 b.join()
24 c.join()
25 print("main - thread is done")
```

```
1 Thread-1 - start
2 Thread-1 - count 0
3 Thread-1 - count 1
4 Thread-2 - start
5 Thread-1 - count 2
6 Thread-2 - count 0
7 Thread-1 - count 3
8 Thread-3 - start
9 main - running 4 threads
10 Thread-2 - count 1
11 Thread-1 - count 4
12 Thread-2 - count 2
13 Thread-1 - count 5
14 Thread-2 - count 3
15 Thread-1 - count 6
16 Thread-2 - count 4
17 Thread-1 - count 7
18 Thread-2 - count 5
19 Thread-1 - count 8
20 Thread-2 - count 6
21 Thread-1 - count 9
22 Thread-2 - count 7
23 Thread-1 - end
24 Thread-2 - count 8
25 Thread-2 - count 9
26 Thread-2 - end
27 Thread-3 - count 0
28 Thread-3 - count 1
29 Thread-3 - count 2
30 Thread-3 - count 3
31 Thread-3 - count 4
32 Thread-3 - count 5
33 Thread-3 - count 6
34 Thread-3 - count 7
35 Thread-3 - count 8
```

```
36 Thread-3 - count 9
37 Thread-3 - end
38 main - thread is done
```

Simple threaded counters (parameterized)

The same as the previous one, but with parameters controlling the numbers of threads and the range of the counter.

```
1  import threading
2  import sys
3
4  num_threads, count_till = 3, 5
5
6  class ThreadedCount(threading.Thread):
7      def run(self):
8          thread = threading.current_thread()
9          print(f'{thread.name} - start')
10         for cnt in range(count_till):
11             print(f'{thread.name} - count {cnt}')
12             print(f'{thread.name} - end')
13         return
14
15  threads = []
16  for ix in range(num_threads):
17      threads.append(ThreadedCount())
18
19  for th in threads:
20      th.start()
21
22  print('main - running {} threads'.format(threading.active_count()))
23
24  for th in threads:
25      th.join()
26  print("main - thread is done")
```

```
1 Thread-1 - start
2 Thread-1 - count 0
3 Thread-1 - count 1
4 Thread-1 - count 2
5 Thread-1 - count 3
6 Thread-1 - count 4
7 Thread-1 - end
8 Thread-2 - start
9 Thread-2 - count 0
10 Thread-2 - count 1
11 Thread-2 - count 2
12 Thread-2 - count 3
13 Thread-2 - count 4
14 Thread-2 - end
15 Thread-3 - start
16 Thread-3 - count 0
17 Thread-3 - count 1
18 Thread-3 - count 2
19 Thread-3 - count 3
20 Thread-3 - count 4
21 Thread-3 - end
22 main - running 1 threads
23 main - thread is done
```

Pass parameters to threads - Counter with attributes

```
1 import threading
2 import sys
3
4 class ThreadedCount(threading.Thread):
5     def __init__(self, name, start, stop):
6         super().__init__()
7         self.name = name
8         self.counter = start
9         self.limit = stop
10        print('__init__ of {} in {}'.format(self.name, threading.current_thread()))
11
12    def run(self):
13        print('start run of {} in {}'.format(self.name, threading.current_thread()))
14        while self.counter < self.limit:
15            print('count {} of {}'.format(self.name, self.counter))
16            self.counter += 1
```

```

17         print('end run   of {} in {}'.format(self.name, threading.current_thread()))
18         .format(self.name, threading.current_thread())
19         return
20
21 foo = ThreadedCount("Foo", 1, 11)
22 bar = ThreadedCount("Bar", 1, 11)
23 foo.start()
24 bar.start()
25 print('main - running {} threads'.format(threading.active_count()))
26 foo.join()
27 bar.join()
28 print("main - thread is done")

```

```

1  __init__  of Foo in <_MainThread(MainThread, started 139645405484864)>
2  __init__  of Bar in <_MainThread(MainThread, started 139645405484864)>
3  start run of Foo in <ThreadedCount(Foo, started 139645391374080)>
4  count Foo of 1
5  count Foo of 2
6  start run of Bar in <ThreadedCount(Bar, started 139645382981376)>
7  count Bar of 1
8  main - running 3 threads
9  count Foo of 3
10 count Bar of 2
11 count Foo of 4
12 count Bar of 3
13 count Foo of 5
14 count Bar of 4
15 count Foo of 6
16 count Bar of 5
17 count Foo of 7
18 count Bar of 6
19 count Foo of 8
20 count Bar of 7
21 count Foo of 9
22 count Bar of 8
23 count Foo of 10
24 count Bar of 9
25 end run   of Foo in <ThreadedCount(Foo, started 139645391374080)>
26 count Bar of 10
27 end run   of Bar in <ThreadedCount(Bar, started 139645382981376)>
28 main - thread is done

```

Create a central counter

```
1  import threading
2  import sys
3  import time
4
5  cnt = 0
6  num = 30
7  limit = 100000
8
9  class ThreadedCount(threading.Thread):
10     def __init__(self):
11         threading.Thread.__init__(self)
12         self.counter = 0
13
14     def run(self):
15         global cnt
16         while self.counter < limit:
17             self.counter += 1
18             cnt += 1
19         return
20
21 start = time.time()
22 threads = [ ThreadedCount() for n in range(num) ]
23 [ t.start() for t in threads ]
24 [ t.join() for t in threads ]
25 end = time.time()
26
27 print("Expected: {}".format(num * limit))
28 print("Received: {}".format(cnt))
29 print("Elapsed: {}".format(end-start))
30
31 # Expected: 3000000
32 # Received: 2659032
33 # Elapsed: 0.437514066696167
```

Lock - acquire - release

```
1  import threading
2  import sys
3  import time
4
5  cnt = 0
6  num = 30
7  limit = 100000
8
9  locker = threading.Lock()
10
11 class ThreadedCount(threading.Thread):
12     def __init__(self):
13         threading.Thread.__init__(self)
14         self.counter = 0
15     def run(self):
16         global cnt
17         while self.counter < limit:
18             self.counter += 1
19             locker.acquire()
20             cnt += 1
21             locker.release()
22         return
23
24 start = time.time()
25 threads = [ ThreadedCount() for n in range(num) ]
26 [ t.start() for t in threads ]
27 [ t.join() for t in threads ]
28 end = time.time()
29
30 print("Expected: {}".format(num * limit))
31 print("Received: {}".format(cnt))
32 print("Elapsed: {}".format(end-start))
33
34 # Expected: 3000000
35 # Received: 3000000
36 # Elapsed: 12.333643198013306
```

Counter - plain

```
1  import sys
2  import time
3
4  cnt = 0
5  num = 30
6  limit = 100000
7
8  class Count():
9      def __init__(self):
10         self.counter = 0
11     def run(self):
12         global cnt
13         while self.counter < limit:
14             self.counter += 1
15             cnt += 1
16         return
17
18 start = time.time()
19 for _ in range(num):
20     c = Count()

Exercise: thread files

- Get a list of files (from the current directory or from all the files in the “slides” repository.
- Process each file:
 1. get size of file
 2. count how many times each character appear in the file.
- The script should accept the number of threads to use.

Exercise: thread URL requests.

In the following script we fetch the URLs listed in a file:

- 1 <https://google.com/>
- 2 <https://youtube.com/>
- 3 <https://facebook.com/>
- 4 <https://baidu.com/>
- 5 <https://twitter.com/>
- 6 <https://instagram.com/>
- 7 <https://wikipedia.com/>
- 8 <https://www.amazon.com/>

```
44 https://duckduckgo.com/
45 https://www.nttdocomo.co.jp/
```

It takes about 1.5-2 sec / URL from home. (It depends on a lot of factors including your network connection.)

```
1  import time
2  import requests
3  import sys
4  from bs4 import BeautifulSoup
5
6  def get_urls(limit):
7      with open('urls.txt') as fh:
8          urls = list(map(lambda line: line.rstrip("\n"), fh))
9          if len(urls) > limit:
10             urls = urls[:limit]
11
12     return urls
13
14 def get_title(url):
15     try:
16         resp = requests.get(url)
17         if resp.status_code != 200:
18             return None, f"Incorrect status_code {resp.status_code} for {url}"
19     except Exception as err:
20         return None, f"Error: {err} for {url}"
21
22     soup = BeautifulSoup(resp.content, 'html.parser')
23     return soup.title.string, None
24
25 def main():
26     if len(sys.argv) < 2:
27         exit(f"Usage: {sys.argv[0]} LIMIT")
28     limit = int(sys.argv[1])
29     urls = get_urls(limit)
30     print(urls)
31     start = time.time()
32
33     titles = []
34     for url in urls:
35         #print(f"Processing {url}")
36         title, err = get_title(url)
37         if err:
```

```

38         print(err)
39     else:
40         print(title)
41     titles.append({
42         "url": url,
43         "title": title,
44         "err": err,
45     })
46     end = time.time()
47     print("Elapsed time: {} for {} pages.".format(end-start, len(urls)))
48     print(titles)
49
50
51 if __name__ == '__main__':
52     main()

```

Create a version of the above script that can use K threads.

Exercise: thread queue

Write an application that handles a queue of jobs in N=5 threads.

Each job contains a number between 0-5.

Each thread takes the next element from the queue and sleeps for the given amount of second (as an imitation of actual work it should be doing). When finished it checks for another job. If there are no more jobs in the queue, the thread can close itself.

```

1  import threading
2  import random
3  import sys
4
5  thread_count = 5
6
7  counter = 0
8  queue = map(lambda x: ('main', random.randrange(5)), range(20))
9  print(queue)

```

If that's done, change the code so that each thread will generate a random number between 0-5 (for sleep-time) and in 33% of the cases it will add it to the central queue as a new job.

Another extension to this exercise is to change the code to limit the number of jobs each thread can execute in its lifetime. When the thread has finished that many jobs it will quit and the main thread will create a new worker thread.

Solution: thread queue

```
1  import threading
2  import random
3  import sys
4  import time
5
6  thread_count = 5
7
8  counter = 0
9  queue = list(map(lambda x: ('main', random.randrange(5)), range(20)))
10 #print(queue)
11
12 locker = threading.Lock()
13
14 class ThreadedCount(threading.Thread):
15     def run(self):
16         global counter
17         my_counter = 0
18         thread = threading.current_thread()
19         print('{} - start thread'.format(thread.name))
20         while (True):
21             locker.acquire()
22             job = None
23             if len(queue) > 0:
24                 counter += 1
25                 my_counter += 1
26                 job = queue[0]
27                 queue[0:1] = []
28             locker.release()
29             if job == None:
30                 print('{} - no more jobs'.format(thread.name))
31                 break
32
33             print('{} - working on job {} ({{}}) from {} sleep for {}'.format(thread.name, counter, my_counter, job[0], job[1]))
34             time.sleep(job[1])
35
36         return
37
38
39 threads = []
40 for i in range(thread_count):
```

```
41     threads.append(ThreadedCount())
42     for t in threads:
43         t.start()
44     for t in threads:
45         t.join()
```

Solution: thread URL requests.

```
1  import time
2  import threading
3  import requests
4  import sys
5  from bs4 import BeautifulSoup
6
7  from fetch_urls import get_urls, get_title
8
9  titles = []
10 locker = threading.Lock()
11
12 class GetURLs(threading.Thread):
13     def __init__(self, urls):
14         threading.Thread.__init__(self)
15         self.urls = urls
16

Marshalling / Serialization

Marshalling (or serialization) is the operation when we take an arbitrary data structure and convert it into a string in a way that we can convert the string back to the same data structure.

Marshalling can be used to save data persistent between execution of the same script, to transfer data between processes, or even between machines. In some cases it can be used to communicate between two processes written in different programming languages.

The `marshal`²⁸⁵ module provides such features but it is not recommended as it was built

²⁸⁵<http://docs.python.org/library/marshal.html>

for internal object serialization for python.

The [pickle](#)²⁸⁶ module was designed for this task.

The [json](#)²⁸⁷ module can be used too.

Fork with random

When the **random** module is loaded it automatically calls `random.seed()` to initialize the random generator. When we create a fork this is not called again and thus all the processes will return the same random numbers. We can fix this by calling `random.seed()` manually.

```
1  import os, time, random
2
3  print('{} - start running'.format(os.getpid()))
4
5  pid = os.fork()
6  if not pid:
7      #random.seed()
8      print('{} - in child'.format(os.getpid()))
9      print(random.random())
10     time.sleep(1)
11     exit(3)
12
13 print('{} - in parent (child pid is {})'.format(os.getpid(), pid))
14 print(random.random())
15
16 done = os.wait()
17 print('{} - Child exited {}'.format(os.getpid(), done))
```

Exercise: fork return data

Create a script that will go over a list of numbers and does some computation on each number.

²⁸⁶<http://docs.python.org/library/pickle.html>

²⁸⁷<https://docs.python.org/library/json.html>

```

1  import sys
2  import time
3  from mymodule import calc
4
5  def main(n):
6      results = {}
7      print(f"do 1-{n}")
8      for ix in range(1, n):
9          results[ix] = calc(ix)
10     return results
11
12 if __name__ == '__main__':
13     if len(sys.argv) < 2:
14         exit(f"Usage: {sys.argv[0]} NUMBER")
15
16     start = time.time()
17     results = main(1+int(sys.argv[1]))
18     end = time.time()
19     total = sum(results.values())
20     print(f"Total: {total}")
21     print("Elapsed time: {}".format(end-start))

```

Allow the child process to return data to the parent process. Before exiting from the child process, serialize the data-structure you want to send back and save in a file that corresponds to the parent process and the child process. (eg. created from the PID of the parent process and the PID of the child process)

In the parent process, when one of the children exits, check if there is a file corresponding to this child process, read the file and de-serialize it.

Solution: fork return data

```

1  import sys
2  import os
3  import json
4  import time
5  from mymodule import calc
6
7  def child(start, end):
8      results = {}
9      for ix in range(start, end):
10         results[ix] = calc(ix)

Asynchronous programming with AsyncIO

Sync chores

We have a number of household chores to do. Each takes a couple of seconds for a machine to do while we have time to do something else. We also have one task, cleaning potatoes, that requires our full attention. It is a CPU-intensive process.

We also have two processes depending each other. We can turn on the dryer only after the washing machine has finished.

```
1  import time
2
3  def boil_water(sec):
4      print(f"Start boiling water for {sec} seconds")
5      time.sleep(sec)
6      print(f"End boiling water for {sec} seconds")
7
8  def washing_machine(sec):
9      print("Start washing machine")
10     time.sleep(sec)
11     print("End washing machine")
12
13  def dryer(sec):
14      print("Start dryer")
15      time.sleep(sec)
16      print("End dryer")
17
18  def dishwasher(sec):
19      print("Start dishwasher")
20      time.sleep(sec)
21      print("End dishwasher")
22
23  def clean_potatoes(pieces):
24      print("Start cleaning potatoes")
25      for ix in range(pieces):
26          print(f"Cleaning potato {ix}")
```

```
27         time.sleep(0.5)
28     print("End cleaning potatoes")
29
30 def main():
31     dishwasher(3)
32     washing_machine(3)
33     dryer(3)
34     boil_water(4)
35     clean_potatoes(14)
36
37 start = time.time()
38 main()
39 end = time.time()
40 print(f"Elapsed {end-start}")
```

```
1  Start dishwasher
2  End dishwasher
3  Start washing machine
4  End washing machine
5  Start dryer
6  End dryer
7  Start boiling water for 4 seconds
8  End boiling water for 4 seconds
9  Start cleaning potatoes
10 Cleaning potato 0
11 Cleaning potato 1
12 Cleaning potato 2
13 Cleaning potato 3
14 Cleaning potato 4
15 Cleaning potato 5
16 Cleaning potato 6
17 Cleaning potato 7
18 Cleaning potato 8
19 Cleaning potato 9
20 Cleaning potato 10
21 Cleaning potato 11
22 Cleaning potato 12
23 Cleaning potato 13
24 End cleaning potatoes
25 Elapsed 20.017353534698486
```

Async chores

```
1  import time
2  import asyncio
3
4  async def boil_water(sec):
5      print(f"Start boiling water for {sec} seconds")
6      await asyncio.sleep(sec)
7      print(f"End boiling water for {sec} seconds")
8
9  async def washing_machine(sec):
10     print(f"Start washing machine for {sec} seconds")
11     await asyncio.sleep(sec)
12     print(f"End washing machine for {sec} seconds")
13     await dryer(3)
14
15  async def dryer(sec):
16     print(f"Start dryer for {sec} seconds")
17     await asyncio.sleep(sec)
18     print(f"End dryer for {sec} seconds")
19
20  async def dishwasher(sec):
21     print(f"Start dishwasher for {sec} seconds")
22     await asyncio.sleep(sec)
23     print(f"End dishwasher for {sec} seconds")
24
25  async def clean_potatoes(pieces):
26     print(f"Start cleaning potatoes for {pieces} pieces")
27     for ix in range(pieces):
28         print(f"Cleaning potato {ix}")
29         time.sleep(0.5)
30         #await asyncio.sleep(0.0001)
31     print(f"End cleaning potatoes for {pieces} pieces")
32
33  async def main():
34     await asyncio.gather(dishwasher(3), washing_machine(3), boil_water(4), clean_pot\
35  atoes(14))
36
37  start = time.time()
38  asyncio.run(main())
39  end = time.time()
40  print(f"Elapsed {end-start}")
```

From the output you can see that we noticed that the washing machine has finished only after we have finished all the potatoes. That's because our potato cleaning process was a long-running CPU-intensive process. This means the dryer only starts working after the potatoes are clean.

```
1 Start dishwasher for 3 seconds
2 Start washing machine for 3 seconds
3 Start boiling water for 4 seconds
4 Start cleaning potatoes for 14 pieces
5 Cleaning potato 0
6 Cleaning potato 1
7 Cleaning potato 2
8 Cleaning potato 3
9 Cleaning potato 4
10 Cleaning potato 5
11 Cleaning potato 6
12 Cleaning potato 7
13 Cleaning potato 8
14 Cleaning potato 9
15 Cleaning potato 10
16 Cleaning potato 11
17 Cleaning potato 12
18 Cleaning potato 13
19 End cleaning potatoes for 14 pieces
20 End dishwasher for 3 seconds
21 End washing machine for 3 seconds
22 Start dryer for 3 seconds
23 End boiling water for 4 seconds
24 End dryer for 3 seconds
25 Elapsed 10.01340126991272
```

If after cleaning each potato we look up for a fraction of a second, if we let the main loop run, then we can notice that the washing machine has ended and we can turn on the dryer before continuing with the next potato. This will allow the dryer to work while we are still cleaning the potatoes.

```
1 Start dishwasher for 3 seconds
2 Start washing machine for 3 seconds
3 Start boiling water for 4 seconds
4 Start cleaning potatoes for 14 pieces
5 Cleaning potato 0
6 Cleaning potato 1
7 Cleaning potato 2
8 Cleaning potato 3
9 Cleaning potato 4
10 Cleaning potato 5
11 End dishwasher for 3 seconds
12 End washing machine for 3 seconds
13 Start dryer for 3 seconds
14 Cleaning potato 6
15 Cleaning potato 7
16 End boiling water for 4 seconds
17 Cleaning potato 8
18 Cleaning potato 9
19 Cleaning potato 10
20 Cleaning potato 11
21 End dryer for 3 seconds
22 Cleaning potato 12
23 Cleaning potato 13
24 End cleaning potatoes for 14 pieces
25 Elapsed 7.02296781539917
```

Explanation

- Single thread
- Single process
- The feeling of parallelism
- Coroutines

* `async/await`

* event loop

* Cooperative Multitasking

- Asynchronous
- non-blocking or synchronous vs blocking (aka “normal”)

Coroutines

* Functions that can be suspended mid-way and allow other functions to run (a generator)

- `async def` is a native coroutine or asynchronous generator
- `async with`
- `async for`

More about asyncio

- [AsyncIO in Real Python](https://realpython.com/async-io-python/)²⁸⁸
- [asyncio](https://docs.python.org/library/asyncio.html)²⁸⁹
- [aiohttp](https://docs.aiohttp.org/)²⁹⁰

Async files

```
1 import aiohttp
2 import asyncio
3
4 async def fetch(session, url):
5     async with session.get(url) as response:
6         return await response.text()
7
8 async def main():
9     async with aiohttp.ClientSession() as session:
10         html = await fetch(session, 'http://python.org')
11         print(html)
12         print("OK")
13
14 asyncio.run(main())
```

```
1 import aiofiles
```

Asynchronous programming with Twisted

About Twisted

- Twisted²⁹¹

Echo

```
1  from twisted.internet import protocol, reactor
2
3  port = 8000
4
5  class Echo(protocol.Protocol):
6      def dataReceived(self, data):
7          text = data.decode('utf8')
8          print(f"Received: {text}")
9          self.transport.write("You said: {}".format(text).encode('utf8'))
10
11 class EchoFactory(protocol.Factory):
12     def buildProtocol(self, addr):
13         return Echo()
14
15 print(f"Listening on port {port}")
16 reactor.listenTCP(port, EchoFactory())
17 reactor.run()
```

²⁹¹<https://twistedmatrix.com/>

```
1  from twisted.internet import reactor, protocol
2  import sys
3
4  if len(sys.argv) < 2:
5      exit("Usage: {sys.argv[0]} TEXT")
6
7  message = sys.argv[1]
8  port = 8000
9
10 class EchoClient(protocol.Protocol):
11     def connectionMade(self):
12         self.transport.write(message.encode('utf8'))
13
14     def dataReceived(self, data):
15         print(f"Server said: {data}")
16         self.transport.loseConnection()
17
18 class EchoFactory(protocol.ClientFactory):
19     def buildProtocol(self, addr):
20         return EchoClient()
21
22     def clientConnectionFailed(self, connector, reason):
23         print("connection failed")
24         reactor.stop()
25
26     def clientConnectionLost(self, connector, reason):
27         print("connection lost")
28         reactor.stop()
29
30 reactor.connectTCP("localhost", port, EchoFactory())
31 reactor.run()
```

Echo with log

```

1  from twisted.internet import protocol, reactor
2
3  port = 8000
4
5  class Echo(protocol.Protocol):
6      def dataReceived(self, data):
7          print("Received: {}".format(data))
8          self.transport.write(data)
9
10 class EchoFactory(protocol.Factory):
11     def buildProtocol(self, addr):
12         print(f"Connection established with {addr}")
13         return Echo()
14
15 print(f"Started to listen on port {port}")
16 reactor.listenTCP(port, EchoFactory())
17 reactor.run()

```

Simple web client

The code behind this example was deprecated. Need to be fixed.

- getPage() returns a “deferred”
- addCallbacks(on_success, on_failure)
- addBoth(on_both) adds callback to both success and failure callback chain

```

1  from twisted.internet import reactor
2  from twisted.web.client import getPage
3  import sys
4
5  def printPage(result):
6      print("Page")
7      print('Size of the returned page is {}'.format(len(result)))
8
9  def printError(error):
10     print("Error")
11     print(f"Error: {error}")
12     #sys.stderr.write(error)
13
14 def stop(result):
15     print('stop')

```

```
16     reactor.stop()
17
18     if (len(sys.argv) != 2):
19         sys.stderr.write("Usage: python " + sys.argv[0] + " <URL>\n")
20         exit(1)
21
22     d = getPage(sys.argv[1])
23     d.addCallbacks(printPage, printError)
24     d.addBoth(stop)
25
26     reactor.run()
27
28     # getPage(sys.argv[1], method='POST', postdata="My test data").
```

31 if __name__ == '__main__':
32     main()

```

Multiprocess and logging

Tested on Windows

```

1  from multiprocessing import Pool
2  import os
3  import logging
4  import logging.handlers
5
6  count = 0
7  def f(x):
8      global count
9      count += 1
10     #print("Input {} in process {}".format(x, os.getpid()))
11     logger = logging.getLogger("app")
12     logger.info("f({}) count {} in PID {}".format(x, count, os.getpid()))
13     return x*x
14
15
16 def prt(z):
17     print(z)
18
19 def setup_logger():

```

```

20     level = logging.DEBUG
21     logger = logging.getLogger("app")
22     logger.setLevel(level)
23     log_file = 'try.log'
24     formatter = logging.Formatter('%(asctime)s - %(levelname)-8s - %(filename)-20s:%(\\
25 lineno)-5d - %(funcName)-22s - %(message)s')
26     ch = logging.FileHandler(log_file)
27     #ch = logging.handlers.TimedRotatingFileHandler(log_file, when='D', backupCount=2)
28     ch.setLevel(level)
29     ch.setFormatter(formatter)
30     logger.addHandler(ch)
31     logger.info("Setup logger in PID {}".format(os.getpid()))
32
33 def main():
34     logger = logging.getLogger('app')
35     logger.info("main")
36
37     with Pool(5) as p:
38         results = p.imap(f, range(110)) # <multiprocessing.pool.IMapIterator object
39         print(results)
40         print('--')
41         for r in results:
42             print(r)
43
44 setup_logger()
45 if __name__ == '__main__':
46     main()

```

Exercise: Process N files in parallel

Create N=100 files 1.txt - N.txt

In each file put L random strings of up to X characters

Write a script that will read all the files for each file and count how many times each digit appears.

Then provide a combined report. First write the script in a single process way.

Then convert it to be able to work with multiprocessing.

Exercise: Process N Excel files in parallel

- Create N Excel files with random 10 random numbers in the first row of each file.
- Write a process that reads the N Excel files and sums up the numbers in each one of them and then sums up the numbers of all the files.

Exercise: Fetch URLs in parallel

- [top-websites](https://www.similarweb.com/top-websites)²⁹³
- Given a file with a list of URLs, collect the title of each site.

41     print(titles)
42
43
44 if __name__ == '__main__':
45     main()
```

Solution: Fetch URLs in parallel

- First create function and use regular map.
- Deal with encoding.
- Replace continue by return, include None in results.
- It has some 2 sec overhead, but then 20 items reduced from 18 sec to 7 sec using pool of 5.

```
1  import time
2  import requests
3  import xml.etree.ElementTree as ET
4  from bs4 import BeautifulSoup
5  from multiprocessing import Pool
6  import os
7
8
9  def get_urls(content):
10     urls = []
11     root = ET.fromstring(content)
12     for child in root:
13         for ch in child:
14             if ch.tag.endswith('loc'):
15                 urls.append(ch.text)
16
17     #print(len(urls)) # 2653
18     MAX = 20
19     if len(urls) > MAX:
20         urls = urls[:MAX]
21
22     return urls
23
24  def get_title(url):
25     resp = requests.get(url)
26     if resp.status_code != 200:
27         print(f"Incorrect status_code {resp.status_code} for {url}")
28         return
29
30     soup = BeautifulSoup(resp.content, 'html.parser')
31     print(soup.title.string)
32     return soup.title.string.encode('utf-8')
33
34
35  def main():

59     main()
```

Multitasking

What is Multitasking?

- [Multitasking](#)²⁹⁶
- A wrapper around threading and os.fork by Ran Aroussi

```
1 pip install multitasking
```

Multitasking example

```
1 import multitasking
2 import time
3 import random
4
5 multitasking.set_max_threads(2)
6
7 @multitasking.task
8 def work(ix, sec):
9     print(f"Start {ix} sleeping for {sec}s")
10    time.sleep(sec)
11    print(f"Finish {ix}")
12
13 if __name__ == "__main__":
14     tasks = (6, 0.7, 0.8, 0.3, 0.4, 3, 0.1)
15     for ix, sec in enumerate(tasks):
16         work(ix+1, sec)
17
18     print("do some work after all the jobs are done")
```

²⁹⁶<https://pypi.org/project/multitasking/>

```
1 Start 1 sleeping for 6s
2 Start 2 sleeping for 0.7s
3 do some work after all the jobs are done
4 Finish 2
5 Start 3 sleeping for 0.8s
6 Finish 3
7 Start 4 sleeping for 0.3s
8 Finish 4
9 Start 5 sleeping for 0.4s
10 Finish 5
11 Start 6 sleeping for 3s
12 Finish 6
13 Start 7 sleeping for 0.1s
14 Finish 7
15 Finish 1
```

Multitasking example with wait

```
1 import multiprocessing
2 import time
3 import random
4
5 multiprocessing.set_max_threads(2)
6
7 @multiprocessing.task
8 def work(ix, sec):
9     print(f"Start {ix} sleeping for {sec}s")
10    time.sleep(sec)
11    print(f"Finish {ix}")
12
13 if __name__ == "__main__":
14     tasks = (6, 0.7, 0.8, 0.3, 0.4, 3, 0.1)
15     for ix, sec in enumerate(tasks):
16         work(ix+1, sec)
17     multiprocessing.wait_for_tasks()
18
19     print("do some work after all the jobs are done")
```

```
1 Start 1 sleeping for 6s
2 Start 2 sleeping for 0.7s
3 Finish 2
4 Start 3 sleeping for 0.8s
5 Finish 3
6 Start 4 sleeping for 0.3s
7 Finish 4
8 Start 5 sleeping for 0.4s
9 Finish 5
10 Start 6 sleeping for 3s
11 Finish 6
12 Start 7 sleeping for 0.1s
13 Finish 7
14 Finish 1
15 do some work after all the jobs are done
```

Multitasking - second loop waits for first one

```
1 import multiprocessing
2 import time
3 import random
4
5 @multiprocessing.task
6 def first(count):
7     sleep = random.randint(1,10)/2
8     if count == 10:
9         sleep = 10
10    print("Start First {} (sleeping for {}s)".format(count, sleep))
11    time.sleep(sleep)
12    print("finish First {} (after for {}s)".format(count, sleep))
13
14 @multiprocessing.task
15 def second(count):
16     sleep = random.randint(1,10)/2
17     print("Start Second {} (sleeping for {}s)".format(count, sleep))
18     time.sleep(sleep)
19     print("finish Second {} (after for {}s)".format(count, sleep))
20
21 if __name__ == "__main__":
22     for i in range(0, 10):
23         first(i+1)
24     multiprocessing.wait_for_tasks()
```

```

25     print('first done')
26
27     for i in range(0, 10):
28         second(i+1)
29
30     multitasking.wait_for_tasks()
31     print('second done')

```

Multitasking counter

```

1  import multitasking
2  import time
3
4
5  multitasking.set_max_threads(10)
6  counter = 0
7
8
9  @multitasking.task
10 def count(n):
11     global counter
12     for _ in range(n):
13         counter += 1

2  Elapsed time 37.231414556503296
```

Improving Performance - Optimizing code

Problems

- Speed
- Memory usage
- I/O (disk, network, database)

Optimization strategy

The 3 rules of optimization

- Don't do it!
- Don't do it!
- Don't do it yet!

Premature optimization is the root of all evil ~ Donald Knuth

Locate the source of the problem

- I/O is expensive! Database access, file access, GUI update
- If memory is full swapping starts - speed decreases

Optimizing tactics

- Choose the Right Data Structure (Dictionary?, Set?, List?)
- Sorting: Decorate Sort Undecorate (DSU) aka. [Schwartzian Transform](https://en.wikipedia.org/wiki/Schwartzian_transform)²⁹⁷.
- String Concatenation: avoid extensive concatenation.
- Loops: for, list comprehension: use generators and iterators.
- Delay expanding range, map, filter, etc. iterables.
- Caching results, memoizing.

Read more [performance tips](https://wiki.python.org/moin/PythonSpeed/PerformanceTips)²⁹⁸

²⁹⁷https://en.wikipedia.org/wiki/Schwartzian_transform

²⁹⁸<https://wiki.python.org/moin/PythonSpeed/PerformanceTips>

DSU: Decorate Sort Undecorate

In Perl it is called Schwartzian transform

```

1  animals = ['chicken', 'cow', 'snail', 'elephant']
2  print(sorted(animals))
3  print(sorted(animals, key=len))
4
5  decorated = [(len(w), w) for w in animals]
6  print(decorated)
7
8  decorated.sort()
9  result = [ d[1] for d in decorated]
10 print(result)
11
12 # at once
13 print( [ d[1] for d in sorted( [(len(w), w) for w in animals] ) ] )

```

```

1  ['chicken', 'cow', 'elephant', 'snail']
2  ['cow', 'snail', 'chicken', 'elephant']
3  [(7, 'chicken'), (3, 'cow'), (5, 'snail'), (8, 'elephant')]
4  ['cow', 'snail', 'chicken', 'elephant']
5  ['cow', 'snail', 'chicken', 'elephant']

```

Profile code

Always profile before starting to optimize!

- [profile](#)²⁹⁹

Slow example

This code does some stuff which was deemed to be “too slow” by some client.
The actual content is not that interesting.

²⁹⁹<http://docs.python.org/library/profile.html>

```
1  import random
2
3  def f():
4      n = 0
5      for i in range(30):
6          n += random.random()
7      return n
8
9  def g():
10     return random.random() * 30
11
12
13 def main(n):
14     text = get_str(n)
15
16     #print(str)
17     text_sorted = sort(text)
18     return text_sorted
19
20 def sort(s):
21     chars = list(s)
22     for i in reversed(range(len(chars))):
23         a = f()
24         b = g()
25         for j in range(i, len(chars)-1):
26             swap(chars, j)
27
28     return ''.join(chars)
29
30 def get_str(n):
31     text = ''
32     for i in range(1, n):
33         text += chr(65 + random.randrange(0, 26))
34     return text
35
36 def swap(lst, loc):
37     if lst[loc] > lst[loc + 1]:
38         lst[loc], lst[loc + 1] = lst[loc + 1], lst[loc]
39
40 if __name__ == '__main__':
41     print(main(1000))
```

profile slow code

```

1 import slow
2 import profile
3
4 profile.run('slow.main(1000)')
```

```

```

³⁰⁸<https://docs.python.org/3/library/weakref.html>

Exercise: benchmark list-comprehension, map, for

- Create several functions that accept a list of numbers from 1 to 1000 and calculate their square:
 - A function with a `for`-loop.
 - A function that uses `map`.
 - A function that uses list-comprehension.
- Feel free to have any other calculation and measure that.
- Send me the code and the results!

Exercise: Benchmark Levenshtein

- Take the implementation of the Levenshtein distance calculations and check which one is faster.

Exercise: sort files

Write a script that given a path to a directory will print the files sorted by date.

If you don't have one large folder, then use `os.walk` to get the path to the files of a whole directory tree.

- Write a simple solution.
- Profile.
- Use [DSU](#)³⁰⁹.

Exercise: compare split words:

We have three ways of splitting a string into words. Using `split`, using `re.split` and by going over it character-by-character.

Which one is the fastest?

³⁰⁹<https://code-maven.com/slides/python-programming/sort-decorate-sort-undecorate>

```
1  import sys
2  import re
3
4  def split_to_words_by_regex(text):
5      return re.split(' ', text)
6
7  def split_to_words_by_split(text):
8      return text.split()
9
10 def split_to_words_by_chars(text):
11     words = []
12     word = ''
13     for ch in text:
14         if ch == ' ':
15             words.append(word)
16             word = ''
17         else:
18             word += ch
19     if word:
20         words.append(word)
21     return words
22
23
24 if __name__ == '__main__':
25     if len(sys.argv) < 2:
26         exit(f"Usage: {sys.argv[0]} FILENAME")
27
28     filename = sys.argv[1]
29     with open(filename) as fh:
30         text = fh.read()
31         res1 = split_to_words_by_split(text)
32         res2 = split_to_words_by_chars(text)
33         res3 = split_to_words_by_regex(text)
34         #print(res1)
35         #print(res2)
36         assert res1 == res2
37         assert res1 == res3
```

Exercise: count words

Given a file count how many times each word appears.
Have two implementations. One using two list and one using a dictionary.

Profile the code and benchmark the two solutions.

See `examples/lists/count_words_two_lists.py` and `examples/dictionary/count_words.py`

GUI with Python/Tk

Sample Tk app

GUI Toolkits

When creating an application there are several ways to interact with the user. You can accept command line parameters.

You can interact on the Standard Output / Standard Input runnin in a Unix Shell or in the Command Prompt of Windows.

Many people, especially those who are using MS Windows, will frown upon both of those. They expect a Graphical User Interface (GUI)

or maybe a web interface via their browser. In this chapter we are going to look at the possibility to create a desktop GUI.

There are plenty of ways to create a GUI in Python. The major ones were listed here, but there are many more. See the additional links.

In this chapter we are going to use the Tk Toolkit.

- [Tk³¹⁰](#)
- [GTK³¹¹](#)
- [Qt³¹²](#)
- [wxWidgets³¹³](#)
- [GUI FAQ³¹⁴](#)
- [GUI Programming³¹⁵](#)

Installation

Tk in Python is actually a wrapper around the implementation in Tcl.

Tcl/Tk usually comes installed with Python. All we need is basically the Tkinter Python module.

³¹⁰<https://docs.python.org/library/tk.html>

³¹¹<http://www.pygtk.org/>

³¹²<https://wiki.python.org/moin/PyQt>

³¹³<http://wxpython.org/>

³¹⁴<https://docs.python.org/3/faq/gui.html>

³¹⁵<https://wiki.python.org/moin/GuiProgramming>

In some Python installations (e.g. Anaconda), Tkinter is already installed. In other cases you might need to install it yourself. For examples on Ubuntu you can use apt to install it.

```
1 sudo apt-get install python3-tk
```

Python Tk Documentation

The documentation of Tk in Python does not cover all the aspects of Tk. If you are creating a complex GUI application you might need to dig in the documentation written for Tcl/Tk.

- [Tk](#)³¹⁶
- [The Tk Command](#)³¹⁷ of [Tcl 8.6](#)³¹⁸
- [Python GUI Geeks for Geeks](#)³¹⁹

In the Unix world where Tk came from the various parts of a GUI application are called widgets. In the MS Windows world they are usually called controls. There are several commonly used Widgets. For example, Label, Button, Entry, Radiobutton, Checkbox. First we are going to see small examples with each one of these Widgets. Then we'll see how to combine them.

Python Tk Button

65
66     app.mainloop()
67
68 main()

```

Exercise: Tk - Calculator one line

Write a Tk application that behaves like a one-line calculator.

It has an entry box where one can enter an expression like “2 + 3” and a button.

When the button is pressed the expression is calculated.

There is another button called “Quit” that will close the application.

Exercise: Tk Shopping list

Create a Tk application that allows you to create a [shopping list](https://code-maven.com/shopping-list)³³¹.

³³¹<https://code-maven.com/shopping-list>

Exercise: Tk TODO list

- Create a Tk application to handle your TODO items.
- A Menu to be able to exit the application
- A List of current tasks.
- A way to add a new task. For a start each task has a title and a status. The status can be “todo” or “done”. (default is “todo”)
- A way to edit a task. (Primarily to change its title).
- A way to mark an item as “done” or mark it as “todo”.
- A way to move items up and down in the list.
- The application should automatically save the items in their most up-to-date state in a “database”. The database can be a JSON file or and SQLite database or anything else you feel fit.

Exercise: Tk Notepad

- Create a Notepad like text editor.
- It needs to have a menu called File with item: New/Open/Save/Save As/Exit
- It needs to have an area where it can show the content of a file. Let you edit it.
- Create a menu called About that displays an about box containing the names of the authors of the app.
- Menu item to Search for text.

Exercise: Tk Copy files

An application that allows you to type in, or select an existing file and another filename for which the file does not exists.

Then copy the old file to the new name.

Exercise: Tk

- Application that accepts a “title” - line of text, a file selected, a new filename (that probably does not exist) and then runs.

Solution: Tk - Calculator one line

```
1  import tkinter as tk
2
3  app = tk.Tk()
4  app.title('Calculator')
5
6  entry = tk.Entry(app)
7  entry.pack()
8
9  def calc():
10     print("clicked")
11     inp = entry.get()
12     print(inp)
13     out = eval(inp)
14     entry.delete(0, tk.END)
15     entry.insert(0, out)
16
17  def close():
18     app.destroy()
19
20  calc_btn = tk.Button(app, text='Calculate', width=25, command=calc)
21  calc_btn.pack()
22
23
24  close_btn = tk.Button(app, text='Close', width=25, command=close)
25  close_btn.pack()
26
27  app.mainloop()
```

```
1  import tkinter as tk
2
3  # This solutions is not ready yet
4
5  app = tk.Tk()
6  app.title('Calculator')
7
8  entry = tk.Entry(app)
9  entry.pack()
10
11  def calc():
12     print("clicked")
13     inp = entry.get()
14     print(inp)
```

```
15     out = eval(inp)
16     entry.delete(0, tk.END)
17     entry.insert(0, out)
18
19 def close():
20     app.destroy()
21     exit()
22
23 def enter(num):
24     entry.insert(tk.END, num)
25
26 def add_button(num, frame):
27     btn = tk.Button(frame, text=num, width=25, command=lambda : enter(num))
28     btn.pack(side="left")
29     buttons[num] = btn
30
31 numbers_frame = tk.Frame(app)
32 numbers_frame.pack()
33 numbers_row = {}
34 numbers_row[1] = tk.Frame(numbers_frame)
35 numbers_row[1].pack(side="top")

37 numbers_row[2].pack(side="top")
38 numbers_row[3] = tk.Frame(numbers_frame)
39 numbers_row[3].pack(side="top")
40 ops_row = tk.Frame(numbers_frame)
41 ops_row.pack(side="top")
42
43 buttons = {}
44
45 add_button(1, numbers_row[1])
46 add_button(2, numbers_row[1])
47 add_button(3, numbers_row[1])
48 add_button(4, numbers_row[2])
49 add_button(5, numbers_row[2])
50 add_button(6, numbers_row[2])
51 add_button(7, numbers_row[3])
52 add_button(8, numbers_row[3])
53 add_button(9, numbers_row[3])
54
55
56 for op in ['+', '-', '*', '/']:
57     add_button(op, ops_row)
```

```
58
59
60 calc_btn = tk.Button(app, text='Calculate', width=25, command=calc)
61 calc_btn.pack()
62
63
64 close_btn = tk.Button(app, text='Close', width=25, command=close)
65 close_btn.pack()
66
67 app.mainloop()
```

Solution: Tk

```
1  import tkinter as tk
2  from tkinter import filedialog
3
4  def run_process():
5      print("---- Start processing ----")
6      title = title_entry.get()
7      print(title)
8      filename = input_file.get()
9      print(filename)
10
11     app.destroy()
12
13 def select_input_file():
14     file_path = filedialog.askopenfilename()
15     filedialog.asksaveasfile()
16     print(file_path)
17     input_file.set(file_path)
18

44 ted as a solution for the exercise.\n\nCopyright: Gabor Szabo")
45
46 menubar = tk.Menu(app)
47
48 menu1 = tk.Menu(menubar, tearoff=0)
49 menu1.add_command(label="New", underline=0, command=run_new)
50 menu1.add_command(label="Open", underline=0, command=run_open)
51 menu1.add_command(label="Save", underline=0, command=run_save)
52 menu1.add_separator()
53 menu1.add_command(label="Exit", underline=1, command=run_exit)
54 menubar.add_cascade(label="File", underline=0, menu=menu1)
55
56 menubar.add_command(label="About", underline=0, command=run_about)
57
58 app.config(menu=menubar)
59
60 text = tk.Text(app)
61 text.pack({"side": "bottom"})
62
63 app.mainloop()
64
65 # TODO: Show the name of the file somewhere? Maybe at the bottom in a status bar?
66 # TODO: Indicate if the file has been changed since the last save?
67 # TODO: Ask before exiting or before replacing the content if the file has not been \
68 saved yet.
69 # TODO: Undo/Redo?
70 # TODO: Search?
71 # TODO: Search and Replace?
```

Simple file dialog

```
1  from tkinter import filedialog
2
3  input_file_path = filedialog.askopenfilename(filetypes=(("Excel files", "*.xlsx"), (\
4  "CSV files", "*.csv"), ("Any file", "*")))
5  print(input_file_path)
6
7  input("Press ENTER to end the script...")
```

Python Pitfalls

Reuse of existing module name

```
1 import random
2
3 print(random.random())
```

```
1 $ python examples/pitfalls/random.py
```

```
1 Traceback (most recent call last):
2   File "examples/pitfalls/random.py", line 1, in <module>
3     import random
4   File ".../examples/pitfalls/random.py", line 3, in <module>
5     print(random.random())
6   TypeError: 'module' object is not callable
```

- Write an example to use random number and call your example **number.py**
- Same with any other module name.
- Lack of multi-level namespaces
- Solution: user longer names. Maybe with project specific names.

Use the same name more than once

```
1 class Corp(object):
2     people = []
3     def add(self, name, salary):
4         Corp.people.append({'name': name, 'salary': salary})
5
6     def total(self):
7         self.total = 0
8         for n in Corp.people:
9             self.total += n['salary']
10        return self.total
11
```

```
12 c = Corp()
13 c.add("Foo", 19)
14 print(c.total())
15
16 c.add("Bar", 23)
17 print(c.total())
```

```
1 $ python examples/pitfalls/corp.py
```

```
1 19
2 Traceback (most recent call last):
3   File "examples/pitfalls/corp.py", line 19, in <module>
4     print(c.total())
5 TypeError: 'int' object is not callable
```

Compare string and number

```
1 x = 2
2 y = "2"
3
4 print(x > y)
5 print(x < y)
```

Python 2 - compares them based on the type of values (wat?)

```
1 $ python examples/pitfalls/compare.py
```

```
1 False
2 True
```

Python 3 - throws exception as expected.

```
1 $ python3 examples/pitfalls/compare.py
```

```
1  Traceback (most recent call last):
2    File "examples/pitfalls/compare.py", line 4, in <module>
3        print(x > y)
4  TypeError: unorderable types: int() > str()
```

Compare different types

```
1  x = 2
2  y = "2"
3
4  print(x == y)
5
6  with open(__file__) as fh:
7      print(fh == x)
```

In both Python 2 and Python 3 these return **False**

```
1  import sys
2
3  hidden = 42    # would be random
4
5  if sys.version_info.major < 3:
6      guess = raw_input('Your guess: ')
7  else:
8      guess = input('Your guess: ')
9
10 if hidden == guess:
11     print("Match!")
```

Will never match. Even if user types in 42. - Hard to debug and understand as there is no error.

Sort mixed data

```
1 from __future__ import print_function
2
3 mixed = [10, '1 foo', 42, '4 bar']
4 print(mixed) # [100, 'foo', 42, 'bar']
5 mixed.sort()
6 print(mixed) # [42, 100, 'bar', 'foo']
```

In Python 2 it “works” in some strange way.

```
1 $ python examples/pitfalls/sort.py
```

```
1 [10, '1 foo', 42, '4 bar']
2 [10, 42, '1 foo', '4 bar']
```

In Python 3 it correctly throws an exception.

```
1 air:python gabor$ python3 examples/pitfalls/sort.py
```

```
1 [10, '1 foo', 42, '4 bar']
2 Traceback (most recent call last):
3   File "examples/pitfalls/sort.py", line 5, in <module>
4     mixed.sort()
5 TypeError: unorderable types: str() < int()
```

Python .NET

IronPython

Python running on the [DLR](#)³³⁴ that is on top of the [CLR](#)³³⁵ of Microsoft.

- [<https://ironpython.net/>]
- [GitHub](#)³³⁶
- Only supports Python 2
- [Iron Python 3](#)³³⁷
- Not ready for production

Use .NET libraries from Python

- [pythonnet](#)³³⁸
- [pythonnet source code](#)³³⁹

```
1 pip install pythonnet
```

The latest Visual Studio is supposed to include [Nuget](#)³⁴⁰, but if you don't have it, you can download it from [Nuget downloads](#)³⁴¹

Make sure `nuget.exe` is somewhere in your PATH:

For example I've created `C:\Bin`, put the `nuget.exe` in this directory and added `C:\Bin` to the PATH.

Then install the compilers using `nuget install Microsoft.Net.Compilers` as suggested on [Roslyn](#)³⁴²
This created the `Microsoft.Net.Compilers.3.4.0` directory in my home directory

Make sure `csc.exe` is somewhere in your PATH or use the full path to it:

`"UsersGabor SzaboMicrosoft.Net.Compilers.3.4.0\tools\csc.exe" /t:library MyMath.cs`

Jython - Python running on the JVM

Jython Installation

- [Jython](#)³⁵¹
- `java -jar jython-installer-2.7.0.jar`
- `~/jython2.7.0/`

Jython Installation

```
1 java -jar ~/jython2.7.0/jython.jar
2
3 java -jar ~/jython2.7.0/jython.jar some.py
```

Jython load Java class

```
1 cd examples/mymath/
2 java -jar ~/jython2.7.0/jython.jar
3 Jython 2.7.0 (default:9987c746f838, Apr 29 2015, 02:25:11)
4 [Java HotSpot(TM) 64-Bit Server VM (Oracle Corporation)] on java1.8.0_60
5 Type "help", "copyright", "credits" or "license" for more information.
6 >>> import Calculator
7 >>> Calculator.add(2, 3)
8 5
9 >>> Calculator.add(10, 3)
10 10
11 >>>
```

Jython load Java class in code

³⁵¹<http://www.jython.org/>

```
1 public class Calculator {
2     public static Integer add(Integer a, Integer b) {
3         if (a == 10) {
4             return 10;
5         }
6         return a+b;
7     }
8
9 }
```

```
1 # use only with Jython
2
3 import Calculator
4 print(Calculator.add(4, 8))
5 print(Calculator.add(10, 8))
```

```
1 cd examples/jython/mymath/
2 java -jar ~/jython2.7.0/jython.jar calc.py
```

Jython test Java class

```
1 import unittest
2 import Calculator
3
4 class TestAdd(unittest.TestCase):
5
6     def test_add(self):
7         self.assertEqual(Calculator.add(4, 8), 12)
8         self.assertEqual(Calculator.add(10, 8), 18)
9         self.assertEqual(Calculator.add(-1, 1), 0)
10
11 if __name__ == '__main__':
12     unittest.main()
13
```

```
1 java -jar ~/jython2.7.0/jython.jar calc.py
2 java -jar ~/jython2.7.0/jython.jar -m unittest discover
```

PIL - Pillow

Install Pillow

- [Pillow](#)³⁵²
- [Pillow on PyPI](#)³⁵³
- [GitHub](#)³⁵⁴

```
1 pip install pillow
```

Create First Image

```
1 from PIL import Image
2
3 img = Image.new('RGB', size=(100, 60), color='#eb8634')
4 img.save('first.png')
5 img.show()      # Using ImageMagic on Linux
```

- Color can be one of the well-known names e.g. “red”
- Color can be RGB in decimal or hex. (RGB=Red Green Blue)

Write Text on Image

³⁵²<https://pillow.readthedocs.io/>

³⁵³<https://pypi.org/project/Pillow/>

³⁵⁴<https://github.com/python-pillow/Pillow>

```
1  from PIL import Image, ImageDraw
2
3  img = Image.new('RGB', size=(100, 60), color='#eb8634')
4
5  draw = ImageDraw.Draw(img)
6  draw.text(
7      text="Some text",
8      xy=(10, 20),
9  )
10
11 img.save('first.png')
12 img.show()
```

Select font for Text on Image

```
1  from PIL import Image, ImageDraw, ImageFont
2
3  img = Image.new(mode='RGB', size=(300, 60), color='#eb8634')
4  font = ImageFont.truetype('Pillow/Tests/fonts/FreeMono.ttf', 20)
5  #font = ImageFont.truetype(f'c:\Windows\Fonts\Candara.ttf', 30)
6  #font = ImageFont.truetype(f'c:\Windows\Fonts\Candarab.ttf', 30)
7  #font = ImageFont.truetype(f'c:\Windows\Fonts\david.ttf', 30)
8
9
10 draw = ImageDraw.Draw(img)
11 draw.text(
12     text="Some text",
13     xy=(10, 20),
14     font=font,
15 )
16
17 img.save('first.png')
18 img.show()
```

Font directories

```
1 Linux: /usr/share/fonts/  
2 Mac OS: /Library/Fonts/  
3 Windows: C:\Windows\fonts
```

Get size of an Image

```
1 from PIL import Image  
2 import sys  
3 if len(sys.argv) !=2:  
4     exit(f"Usage: {sys.argv[0]} FILENAME")  
5  
6 in_file = sys.argv[1]  
7  
8 img = Image.open(in_file)  
9 print(img.size)      # a tuple  
10 print(img.size[0]) # width  
11 print(img.size[1]) # height
```

Get size of text

```
1 font = ImageFont.truetype(  
2     'path/to/font.ttf', size  
3 )  
4 size = font.getsize(text)
```

Resize an existing Image

```
1 from PIL import Image  
2  
3 in_file = 'in.png'  
4 out_file = 'new.png'  
5  
6 img = Image.open(in_file)  
7  
8 size = (img.size[0] / 2, img.size[1] / 2)  
9 img.thumbnail(size)  
10  
11 img.save(out_file)
```

Crop an existing Image

```

1  from PIL import Image
2
3  in_file = 'in.png'
4  out_file = 'out.png'
5
6  img = Image.open(in_file)
7  width, height = img.size
8  width, height = img.size
9
10 # crop
11 # 10 pixels from the left
12 # 20 pixels from the top
13 # 30 pixels from the right
14 # 40 pixels from the bottom
15
16 cropped = img.crop((10, 20, width - 30, height - 40))
17 cropped.save(out_file)
18 cropped.show()

```

Combine two images

- Load one image from file
- Create a plain background
- Put the loaded image on the background
- Save the combined image

Rotated text

```

1  from PIL import Image, ImageDraw, ImageFont, ImageOps
2
3  img = Image.new(mode='RGB', size=(400, 200), color='#eb8634')
4
5  font = ImageFont.truetype('Pillow/Tests/fonts/FreeSansBold.ttf', 30)
6
7  text_layer = Image.new('L', (330, 50))
8  draw = ImageDraw.Draw(text_layer)
9  draw.text((30, 0), "Text slightly rotated", font=font, fill=255)
10
11 rotated_text_layer = text_layer.rotate(10.0, expand=1)
12 img.paste( ImageOps.colorize(rotated_text_layer, (0,0,0), (10, 10,10)), (42,60), ro\
13 tated_text_layer)
14 img.show()

```

Rotated text in top-right corner

TODO: fix this

```

1  from PIL import Image, ImageDraw, ImageFont, ImageOps
2
3  width = 400
4  height = 200
5  start = 100
6  end    = 50
7
8  img = Image.new(mode='RGB', size=(width, height), color='#FAFAFA')
9
10 stripe_color = "#eb8634"
11 draw = ImageDraw.Draw(img)
12 draw.polygon([(width-start, 0), (width-end, 0), (width, end), (width, start) ], fill\
13 =stripe_color)
14
15
16 font = ImageFont.truetype('Pillow/Tests/fonts/FreeSansBold.ttf', 30)
17 text_layer = Image.new('RGB', size=(100, 100), color=stripe_color)
18
19 draw = ImageDraw.Draw(text_layer)
20 text = "Free"
21 size = draw.textsize(text=text, font=font)
22 # print(size)
23 draw.text( xy=(20, 0), text=text, font=font, fill=1)
24 #
25 rotated_text_layer = text_layer.rotate(-45.0, expand=0)
26 rotated_text_layer.show()
27 #img.paste( ImageOps.colorize(rotated_text_layer, (0,0,0), (10, 10,10)), (42,60), r\
28 otated_text_layer)
29 #img.paste(im = rotated_text_layer, box=(300, 0))
30 #img.paste(im = text_layer, box=(300, 0))
31 #img.show()
```

Embed image (put one image on another one)

```
1  from PIL import Image
2
3  in_file = 'python.png'
4
5  width = 600
6  height = 300
7  background = Image.new(mode='RGB', size=(width, height), color='#AAFAFA')
8
9  img = Image.open(in_file)
10 (emb_width, emb_height) = img.size
11 print(emb_width)
12 print(emb_height)
13
14 # slightly off the lower right corner of the background image
15 # using the image as the mask makes its background transparent
16 background.paste(im = img, box=(width-emb_width-10, height-emb_height-10), mask=img)
17
18 background.show()
```

Draw a triangle

```
1  from PIL import Image, ImageDraw
2
3  img = Image.new(mode='RGB', size=(800, 450), color='#eb8634')
4
5  draw = ImageDraw.Draw(img)
6  draw.polygon([(800, 275), (800, 450), (300, 450) ])
7
8  img.save('first.png')
9  img.show()
```

Draw a triangle and write text in it

```
1  from PIL import Image, ImageDraw, ImageFont
2
3  img = Image.new(mode='RGB', size=(800, 450), color='#eb8634')
4
5  draw = ImageDraw.Draw(img)
6  draw.polygon([(800, 275), (800, 450), (300, 450) ], fill = (255, 255, 255))
7
8  font = ImageFont.truetype('Pillow/Tests/fonts/FreeSansBold.ttf', 30)
9
10 draw.text((500, 400), 'Hello from Python', (0, 0, 0), font=font)
11
12
13 img.save('first.png')
14 img.show()
```

Draw a triangle and write rotated text in it

```
1  from PIL import Image, ImageDraw, ImageFont, ImageOps
2
3  img = Image.new(mode='RGB', size=(400, 200), color='#eb8634')
4
5  # draw = ImageDraw.Draw(img)
6  # draw.polygon([(800, 275), (800, 450), (300, 450) ], fill = (255, 255, 255))
7  #
8  #
9  #font = ImageFont.load_default()
10 font = ImageFont.truetype('Pillow/Tests/fonts/FreeSansBold.ttf', 30)
11 # txt = Image.new('L', (500, 500))
12 # d = ImageDraw.Draw(txt)
13 # d.text((300, 400), 'Hello from Python', font=font, color="white")
14 # w=txt.rotate(17.5, expand=1)
15 #
16 # img.paste(txt)
17 # img.paste( ImageOps.colorize(w, (0,0,0), (255,255,84)), (242,60), w)

TODO

<http://web.archive.org/web/20130115175340/http://nadiana.com/pil-tutorial-basic-advanced-drawing>

- Make the background color change from top to bottom
- Add straight lines to existing images
- Blur image
- Add rectangular to area on existing image
- Draw other simple images

³⁵⁶<http://nadiana.com/>

FAQ

How not to name example scripts?

Don't - by mistake - call one of your files the same as a module you will be loading.

For example `random.py` is a bad idea if you will `import random`.

Your code will try to locate `random.py` to load, but will find itself and not the one that comes with Python.

Python will also create a `random.pyc` file - a compiled file - and it will take time till you recall this and delete that too.

Till then the whole thing will seem to be broken.

Platform independent code

In general Python is platform independent, but still needs some care to make sure you don't step on some aspects of Operating System or the file system that works differently on other OS-es.

- Filenames are case sensitive on some OS-es (e.g. Windows). They used to be restricted to 8.3. Make sure you are within the restriction of every OS you might want to use.
- Directory path: (slash or backslash or something else?) use the `os.path` methods.
- `os.path.expanduser('~')` works on both Linux and Windows, but the root of a Linux/Unix file system starts with a slash (/) and on Windows it is `c:\` and `d:\` etc.
- On Linux/Unix you have user 'root' and on Windows 'Administrator'
- File permissions are different on Linux and Windows.
- Stay away from OS specific calls, but as a last resort use `os.name` or `sys.platform` to figure out which os is this. `os.name` is 'posix' on Linux and 'nt' on Windows.
- For GUI use `wxWindows` that has a native look on Windows and Gnome look on Linux.
- Pay attention to any 32/64 bit issues. Big/Little Endian issues.
- Some modules might be OS specific. Check the documentation.
- Pay attention to the use of `os.system` and `subsystem` modules.

How to profile a python code to find causes of slowness?

Use one of these modules:

- cProfile is in C. It is faster and preferable.
- profile

pdb = Python Debugger

Include the following code in your script at any point, and run the script as you'd do normally. It will stop at the given point and enter the debugger.

```
1 import pdb; pdb.set_trace()
```

[pdb](#)³⁵⁷

Avoid Redefining functions

Can I tell python to stop compilation when someone is redefining a function?
Or at least give me a warning?

Use `pylint` for that

³⁵⁷<http://docs.python.org/library/pdb.html>

Appendix

print_function

```
1 from __future__ import print_function
2
3 print(23)
```

Dividers (no break or continue)

We will see how break and continue work, but first let's see a loop to find all the dividers on a number n.

```
1 i = 2
2 n = 3*5*7
3 while i < n:
4     if (n / i) * i == n:
5         print('{:2} divides {}'.format(i, n))
6     i = i + 1
```

```
1  3 divides 105
2  5 divides 105
3  7 divides 105
4 15 divides 105
5 21 divides 105
6 35 divides 105
```

Lambdas

```
1 a = lambda x: True
2 b = lambda x: False
3 c = lambda x: x
4 #c = lambda x: return
5 #c = lambda x: pass
6 d = lambda x: c(x)+c(x)
7
8 print(a(1))
9 print(b(1))
10 print(c(42))
11 print(d(21))
```

Abstract Class

```
1 import abc
2
3 class Port():
4     __metaclass__ = abc.ABCMeta
5
6     @abc.abstractmethod
7     def num(self):
8         pass
9
10 class HTTPPort(Port):
11     def num(self):
12         return 80
13
14 class FTPPort(Port):
15     def num(self):
16         return 21
17
18 class ZorgPort(Port):
19     def nonum(self):
20         return 'zorg'
21
22 f = FTPPort()
23 print(f.num())
24 h = HTTPPort()
25 print(h.num())
26 z = ZorgPort()
27 # Traceback (most recent call last):
28 #   File "abstract.py", line 26, in <module>
```

```

29 #     z = ZorgPort()
30 # TypeError: Can't instantiate abstract class ZorgPort with abstract methods num
31
32
33 print(z.num())

```

Remove file

`os.remove`³⁵⁸ or
`os.unlink`³⁵⁹

Modules: more

- `sys.modules` to list loaded modules
- `imp.reload` to reload module (Just reload before 3.3)

```

1  import __builtin__
2
3  def xx(name):
4      print("hello")
5  __builtin__.__import__ = xx;
6
7  print('body')
8  def f():
9      print("in f")

```

```

1  import sys
2
3  print('mod' in sys.modules) # False
4
5  import mod
6  print('mod' in sys.modules) # True
7  print(sys.modules['mod'])
8      # <module 'mod' from '/stuff/python/examples/modules/mod.py'>
9
10 print(sys.modules["sys"])    # <module 'sys' (built-in)>

```

³⁵⁸<https://docs.python.org/library/os.html#os.remove>

³⁵⁹<https://docs.python.org/library/os.html#os.unlink>

Progress bar

```
1 # http://stackoverflow.com/questions/3173320/text-progress-bar-in-the-console
2 import time, sys
3
4 for i in range(10):
5     sys.stdout.write('\r' + '=' * i)
6     sys.stdout.flush()
7     time.sleep(1)
```

from future

```
1 from __future__ import print_function
2 from __future__ import division
```

or

```
1 from __future__ import print_function, division
```

See also [future](#)³⁶⁵

We cannot import everything that is in **future**, because we don't know what will be in **future** in the future...
and we don't want to blindly change the behaviour of Python.

Variable scope

- There are two scopes: outside of all functions and inside of a function.
- The first assignment to a variable defines it.
- Variables that were declared outside all functions can be seen inside, but cannot be changed.
- One can connect the outside name to an inside name using the 'global' keyword.
- if and for blocks don't provide scoping.

```
1  a = 23
2
3  def main():
4      global b
5      b = 17
6      c = 42
7      print('a:', a)    # a: 23
8      print('b:', b)    # b: 17
9      print('c:', c)    # c: 42
10
11     if True:
12         print('a:', a)    # a: 23
13         print('b:', b)    # b: 17
14         b = 99
15         print('b:', b)    # b: 99
16         print('c:', c)    # c: 42
17
18     print('a:', a)    # a: 23
19     print('b:', b)    # b: 99
20     print('c:', c)    # c: 42
21
22
23  main()
24
25  print('a:', a)    # a: 23
26  print('b:', b)    # b: 99
27  print('c:', c)    # c:
28  # Traceback (most recent call last):
29  #   File "examples\basics\scope.py", line 27, in <module>
```

```
30 #     print 'c:', c # c:
31 # NameError: name 'c' is not defined
```

global scope

scope

```
1 # x is global
2
3 x = 1
4 print(x, "- before sub")
5
6 def f():
7     #print(x, "- inside before declaration") # UnboundLocalError
8     x = 2
9     print(x, "- inside sub")
10
11 print(x, "- after sub declaration")
12
13 f()
14
15 print(x, "- after calling sub")
16
17 # 1 - before sub
18 # 1 - after sub declaration
19 # 2 - inside sub
20 # 1 - after calling sub
```

```
1 # x is global
2
3 def f():
4     #print(x, "- inside before declaration") # UnboundLocalError
5     x = 2
6     print(x, "- inside sub")
7
8 x = 1
9 print(x, "- before calling sub")
10
```

```
11 print(x, "- after sub declaration")
12
13 f()
14
15 print(x, "- after calling sub")
16
17 # 1 - before calling sub
18 # 1 - after sub declaration
19 # 2 - inside sub
20 # 1 - after calling sub
```

If we declare a variable outside of all the subroutines, it does not matter if we do it before the sub declaration, or after it. In neither case has the global variable any presence inside the sub.

```
1 def f():
2     x = 2
3     print(x, "- inside sub")
4
5 # print(x, " - after sub declaration") # NameError
6
7 f()
8
9 # print(x, " - after calling sub")    # NameError
10
11 # 2 - inside sub
```

A name declared inside a subroutine is not visible outside.

```
1 def f():
2     global x
3     # print(x) # NameError
4     x = 2
5     print(x, "- inside sub")
6
7 # print(x, " - after sub declaration") # NameError
8
9 f()
10
11 print(x, "- after calling sub")
12
13 # 2 - inside sub
14 # 2 - after calling sub
```

Unless it was marked using the global word.

type

```
1 x = 2
2 y = '2'
3 z = [2, '2']
4 d = {}
5
6 def f():
7     pass
8 l = lambda q: q
9
10 class Cold():
11     pass
12 cold = Cold()
13
14 class Cnew(object):
15     pass
16 cnew = Cnew()
17
18 # r = xrange(10) # Python 3 does not have xrange
19
20 print(type(x)) # <type 'int'>
```

```

21 print(type(y)) # <type 'str'>
22 print(type(z)) # <type 'list'>
23 print(type(d)) # <type 'dict'>
24 print(type(f)) # <type 'function'>
25 print(type(l)) # <type 'function'>
26 print(type(Cold)) # <type 'classobj'>
27 print(type(cold)) # <type 'instance'>
28 print(type(Cnew)) # <type 'type'>
29 print(type(cnew)) # <class '__main__.Cnew'>
30 #print(type(r)) # <type 'xrange'>
31
32 print(type(x).__name__) # int
33 print(type(y).__name__) # str
34 print(type(z).__name__) # list

```

Look deeper in a list

```

1 x = ['abcd', 'efgh']
2 print(x) # ['abcd', 'efgh']
3
4 print(x[0:1]) # ['abcd']
5 print(x[0]) # 'abcd'
6
7 print(x[0][0]) # a
8 print(x[0][1]) # b
9 print(x[0][0:2]) # ab

```

Exercise: iterators - count

- Reimplement the count functions of itertools using iterator class.

(We have this as one of the example)

Simple function (before generators)

TODO: probably not that interesting

```
1 def number():
2     return 42
3
4 print(number())    # 42
5 print(number())    # 42
6 print(number())    # 42
```

```
1 def number():
2     return 42
3     return 19
4     return 23
5
6 print(number()) # 42
7 print(number()) # 42
8 print(number()) # 42
```

Other slides

Other slides

Some slides that used to be part of the material and they might return to be there, but for now they were parked here.

Atom for Python

Some details about the Atom editor. You can freely skip this part. Personally I don't use it now.

- [Atom](#)³⁶⁶

Autocomplete

- `apm install autocomplete-python`

Autocomplete

- `easy_install jedi`
- `apm install autocomplete-plus-python-jedi`

Linter

- `easy_install flake8`
- `easy_install flake8-docstrings`
- `apm install linter`
- `apm install linter-flake8`

[source](#)³⁶⁷

³⁶⁷<http://www.marinamele.com/install-and-configure-atom-editor-for-python>

IDLE - Integrated DeveLopment Environment

- Python shell
- Better editing
- Limited debugger
- c:\Python27\Lib\idlelib\idle.bat
- C:\Users\Gabor\AppData\Local\Programs\Python\Python35\Lib\idlelib\idle.bat

sh-bang - executable on Linux/Apple

```
1 #!/usr/bin/env python
2
3 print("Hello World")
```

- The first line starting with # is needed if you want to have a file that can be executed without explicitly typing in python as well.
- Make your file executable: `chmod u+x hello_ex.py`
- Run like: `./hello_ex.py`
- In order to run it as `hello_ex.py` it needs to be located in one of the directories listed in the PATH environment variable.

Strings as Comments

marks single line comments.

There are no real multi-line comments in Python, but we can use triple-quotes to create multi-line strings and if they are not part of another statement, they will be disregarded by the Python interpreter. Effectively creating multi-line comments.

```
1 print("hello")
2
3 'A string which is disregarded'
4
5 print(42)
6
7 '''
8     Using three single-quotes on both ends (a triple-quoted string)
9     can be used as a multi-line comment.
10 '''
11
12 print("world")
```

pydoc

If you really want it, you can also read some of the documentation on the command line, but unless you are locked up some place without Internet connection, I don't recommend this.

Type pydoc. On Windows, you might need to create the following file and put it in a directory in your PATH. (see `echo %PATH%`)

```
1 @python c:\Python27\Lib\pydoc.py %*
```

How can I check if a string can be converted to a number?

There is no `is_int`, we just need to try to convert and catch the exception, if there is one.

```
1 def is_float(val):
2     try:
3         num = float(val)
4     except ValueError:
5         return False
6     return True
7
8 def is_int(val):
9     try:
10        num = int(val)
11    except ValueError:
12        return False
```

```

13     return True
14
15 print( is_float("23") )      # True
16 print( is_float("23.2") )   # True
17 print( is_float("23x") )    # False
18 print( '-----' )          # -----
19 print( is_int("23") )       # True
20 print( is_int("23.2") )     # False
21 print( is_int("23x") )     # False

```

Spyder Intro

- iPython console (bottom right)
- Spyder-Py2 / Preferences / Console / Advanced Settings
- Save the file (Ctrl-S / Command-S)
- Run/Run (F5)
- F9 - execute selected text (e.g. we can execute a function definition after we've changed it)
- TAB for autocomplete names of already existing variables.

```

1 print("abc")
2 "abc".          shows the available methods.
3 "abc".center    Command-I will explain what is "center"

```

Interactive Debugging

```

1 def f(a, b):
2     c = a + b
3     d = a * b
4     return c+d
5
6 def run():
7     print(f(2, 3))
8
9     import code
10    code.interact(local=locals())
11
12    print(f(19, 23))
13
14 run()

```

Parameter passing

```
1 def hello(name):
2     msg = name + '!!!!'
3     print('Hello ' + msg)
4
5 hello('Foo')
6 hello('Bar')
```

```
1 Hello Foo!!!!
```

Command line arguments and main

```
1 import sys
2
3 def hello(name):
4     msg = name + '!!!!'
5     print('Hello ' + msg)
6
7 def main():
8     hello(sys.argv[1])
9
10 main()
```

Run as **python argv.py Foo**

Later we'll see the `argparse` module that can handle command line arguments in a better way.

Infinite loop

```
1 i = 0
2 while True:
3     i += 1
4     print(i)
5
6 print("done")
```

break

```
1 i = 0
2 while True:
3     print(i)
4     i += 1
5     if i >= 7:
6         break
7
8 print("done")
```

```
1 0
2 1
3 2
4 3
5 4
6 5
7 6
8 done
```

continue

```
1 i = 0
2 while True:
3     i += 1
4
5     if i > 3 and i < 8:
6         continue
7
8     if i > 10:
9         break
10    print(i)
```

```
1 1
2 2
3 3
4 8
5 9
6 10
```

While with many conditions

```
1 while (not found_error) and (not found_warning) and (not found_exit):
2     do_the_real_stuff()
3
4 while True:
5     line = get_next_line()
6
7     if found_error:
8         break
9
10    if found_warning:
11        break
12
13    if found_exit:
14        break
15
16    do_the_real_stuff()
```

while loop with many conditions

```
1 while True:
2     line = get_next_line()
3
4     if last_line:
5         break
6
7     if line is empty:
8         continue
9
10    if line_has_a_hash: # at the beginning:
11        continue
12
13    if line_has_two_slashes: // at the beginning:
14        continue
15
16    do_the_real_stuff()
```

Format with conversion (stringification with str or repr)

Adding !s or !r in the place-holder we tell it to call the str or repr method of the object, respectively.

- repr (**repr**) Its goal is to be unambiguous
- str (**str**) Its goal is to be readable
- The default implementation of both are useless
- Suggestion
- Difference between **str** and **repr**³⁶⁸

```

1 class Point:
2     def __init__(self, a, b):
3         self.x = a
4         self.y = b
5
6 p = Point(2, 3)
7 print(p)                # <__main__.Point object at 0x10369d750>
8 print("{}".format(p))   # <__main__.Point object at 0x10369d750>
9 print("{!s}".format(p)) # <__main__.Point object at 0x10369d750>
10 print("{!r}".format(p)) # <__main__.Point object at 0x10369d750>

```

```

17             cr = func(*args, **kwargs)
18             cr.next()
19             return cr
20         return start
21
22     # example use
23     if __name__ == '__main__':
24         @coroutine
25         def printer():
26             while True:
27                 event = (yield)
28                 print(event)
29
30     xml.sax.parse(file, EventHandler(printer()))
```

Getting the class name of an object

How to find out which class an object (instance) belongs to?

```
1  import re
2
3  a = 2
4  b = "3"
5  c = 2.3
6
7  m = re.search(r'\d', str(c))
8
9  print(a.__class__)    # <type 'int'>
10 print(b.__class__)    # <type 'str'>
11 print(c.__class__)    # <type 'float'>
12
13 print(type(a))        # <type 'int'>
14 print(type(b))        # <type 'str'>
15 print(type(c))        # <type 'float'>
16
17
18 print(a.__class__.__name__)    # int
19 print(b.__class__.__name__)    # str
20 print(c.__class__.__name__)    # float
21
22 print(re.__class__.__name__)   # module
23 print(m.__class__.__name__)    # SRE_Match or Match
```

Inheritance - super

We can also call super() passing a different class name

```
1  class Point():
2      def __init__(self, x, y):
3          print('__init__ of point')
4          self.x = x
5          self.y = y
6
7  class Circle(Point):
8      def __init__(self, x, y, r):
9          print('__init__ of circle')
10         super().__init__(x, y)
11         self.r = r
```

```

12
13 class Ball(Circle):
14     def __init__(self, x, y, r, z):
15         print('__init__ of ball')
16         #super(Circle, self).__init__(x, y) # r
17         Point.__init__(self, x, y) # r
18         self.z = z
19
20
21 b = Ball(2, 3, 10, 7)
22 print(b)
23
24 # __init__ of ball
25 # __init__ of point
26 # <__main__.Ball object at 0x10a26f190>

```

Inheritance - super - other class

We cannot pass any class name to super()

```

1 class Point:
2     def __init__(self, x, y):
3         print('__init__ of point')
4         self.x = x
5         self.y = y
6
7 class Circle(Point):
8     def __init__(self, x, y, r):
9         print('__init__ of circle')
10        super(Circle, self).__init__(x, y)
11        self.r = r
12
13 class Ball(Circle):
14     def __init__(self, x, y, r, z):
15         print('__init__ of ball')
16         super(Zero, self).__init__(x, y)
17         self.z = z
18
19 class Zero:

```

```

20     def __init__(self, x, y):
21         print('really?')
22     pass
23
24
25 b = Ball(2, 3, 10, 7)
26 print(b)
27
28 # __init__ of circle
29 # Traceback (most recent call last):
30 #   File "bad_shapes.py", line 25, in <module>
31 #     b = Ball(2, 3, 10, 7)
32 #   File "bad_shapes.py", line 16, in __init__
33 #     super(Zero, self).__init__(x, y)
34 # TypeError: super(type, obj): obj must be an instance or subtype of type

```

iterator - pairwise

```

1 def pairwise(iterable):
2     "s -> (s0,s1), (s2,s3), (s4, s5), ..."
3     i = 0
4     while i+1 < len(iterable):
5         t = (iterable[i], iterable[i+1])
6         i += 2
7         yield t
8
9 l = [1, 2, 3, 4, 5, 6]
10 for x, y in pairwise(l):
11     print(f"{x} + {y} = {x + y}")

```

iterator - grouped

```

1 def grouped(iterable, n):
2     """s -> (s0,s1,s2,...sn-1),
3         (sn,sn+1,sn+2,...s2n-1),
4         (s2n,s2n+1,s2n+2,...s3n-1), ..."""
5
6     i = 0
7     while i+n-1 < len(iterable):
8         t = tuple(iterable[i:i+n])
9         i += n
10        yield t
11
12 l = [1, 2, 3, 4, 5, 6, 7, 8, 9]
13 for x, y, z in grouped(l, 3):
14     print("{} + {} + {} = {}".format(x, y, z, x + y + z))

```

```

1 1 + 2 + 3 = 6
2 4 + 5 + 6 = 15
3 7 + 8 + 9 = 24

```

itertools - groupby

Group elements

```

1 from itertools import groupby
2
3 def groupby_even_odd(items):
4     f = lambda x: 'even' if x % 2 == 0 else 'odd'
5     gb = groupby(items, f)
6     print(gb)
7     for k, items in gb:
8         print('{}: {}'.format(k, ','.join(map(str, items))))
9
10 groupby_even_odd([1, 3, 4, 5, 6, 8, 9, 11])

```

Circular references

circular references are cleaned up by the garbage collector
but maybe not all the memory is given back to the OS, and it can take some time to clean them up.

```

1  import time
2
3
4  def create_pair():
5      a = {'name' : 'Foo'}
6      b = {'name' : 'Bar'}
7      a['pair'] = b
8      b['pair'] = a
9      #print(a)
10
11
12  for i in range(1, 30000000):
13      create_pair()
14
15  print("let's sleep now a bit")
16  time.sleep(20)

```

but weakref might expedite the cleanup. See also the gc module and if I can show it
<http://stackoverflow.com/questions/2428301/should-i-worry-about-circular-references-in-python>

Context managers: with (file) experiments

```

1  with open('out.txt', 'w') as h:
2      h.write("hello\n")
3
4  h = open('out.txt')
5  print(h.read())

1  f = open('out.txt', 'w')
2  f.write("hello\n")
3  f.close()
4
5  # for line in open("myfile.txt"):
6  #     print line,
7  # the file is closed only when script ends

```

itertools - izip

Python 3 does not need this any more as the built-in zip is already an iterator.

Combine two unbounded lists

```

1  from itertools import izip, count
2
3  for t in izip(count(start=1, step=1), count(start=10, step=-1)):
4      print("{:3} + {:3} = {}".format(t[0], t[1], t[0]+t[1]))
5      if t[0] > 20:
6          break
7  #  1 + 10 = 11
8  #  2 +  9 = 11
9  #  3 +  8 = 11
10 #  4 +  7 = 11
11 #   ...
12 # 20 + -9 = 11
13 # 21 + -10 = 11

```

mixing iterators

Combine three unbounded lists

```

1  from itertools import izip, count
2  from my_iterators import fibo, alter
3
4  mixer = izip(count(), fibo(), alter())
5
6  for mix in mixer:
7      print("{:3}  {:3}  {:3}".format(*mix))
8      if mix[0] >= 8: break
9
10 # 0    1    1
11 # 1    1   -2
12 # 2    2    3
13 # 3    3   -4
14 # 4    5    5
15 # 5    8   -6
16 # 6   13    7
17 # 7   21   -8
18 # 8   34    9

```

mixing iterators

```

1  def fibo():
2      a, b = 1, 1
3      while True:
4          yield a
5          a, b = b, a+b
6
7  def alter():
8      n = 1
9      while True:
10         yield n
11         if n < 0:
12             n -= 1
13         else:
14             n += 1
15         n *= -1

```

itertools - pairwise

```

1  from itertools import izip
2
3  def pairwise(iterable):
4      "s -> (s0,s1), (s2,s3), (s4, s5), ..."
5      a = iter(iterable)
6      return izip(a, a)
7
8  l = [1, 2, 3, 4, 5, 6, 7]
9  for x, y in pairwise(l):
10     print("{} + {} = {}".format(x, y, x + y))
11
12     # 1 + 2 = 3
13     # 3 + 4 = 7
14     # 5 + 6 = 11

```

Every 2 element from a list. We are using the exact same iterator object in both places of the `izip()` call,

so every time `izip()` wants to return a tuple, it will fetch two elements from the same iterator.

Iterating over every two elements in a list³⁷¹

itertools - grouped

Every N element from a list

³⁷¹<http://stackoverflow.com/questions/5389507/iterating-over-every-two-elements-in-a-list>

```

1  from itertools import izip
2
3  def grouped(iterable, n):
4      '''s -> (s0,s1,s2,...sn-1),
5              (sn,sn+1,sn+2,...s2n-1),
6              (s2n,s2n+1,s2n+2,...s3n-1), ...'''
7      a = iter(iterable)
8      iterators = [a] * n
9      return izip(*iterators)
10
11 l = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
12 for x, y, z in grouped(l, 3):
13     print("{} + {} + {} = {}".format(x, y, z, x + y + z))
14
15 # 1 + 2 + 3 = 6
16 # 4 + 5 + 6 = 15
17 # 7 + 8 + 9 = 24

```

range vs xrange in Python

```

1  from __future__ import print_function
2  import sys
3
4  r = range(1000)
5  x = xrange(1000)
6
7  for v in r:    # 0..999
8      pass
9  for v in x:    # 0..999
10     pass
11
12 print(sys.getsizeof(r)) # 8072
13 print(sys.getsizeof(x)) # 40

```

In Python 2 range creates a list of values range(from, to, step) and xrange creates an iterator. In Python 3 range creates the iterator and if really necessary then list(range()) can create the list.

[range vs. xrange in Python](http://code-maven.com/range-vs-xrange-in-python)³⁷²

profile (with hotshot) slow code

It was experimental and dropped from Python 3

³⁷²<http://code-maven.com/range-vs-xrange-in-python>

- <https://docs.python.org/2/library/hotshot.html>

```

1  import slow
2  import os
3  import hotshot, hotshot.stats
4
5  prof = hotshot.Profile("slow.prof")
6  prof.runcall(slow.main, 1000)
7  prof.close()
8  stats = hotshot.stats.load("slow.prof")
9  stats.strip_dirs()
10 stats.sort_stats('time', 'calls')
11 stats.print_stats(20)
12
13 os.remove("slow.prof")

```

```

Python Descriptors

A more manual way to implement the `property()` functionality we have just seen.
Use cases:

- Implement type-checking and/or value checking for attribute setters ()
- [Descriptors](#)³⁷⁶
- [Descriptor HowTo Guide](#)³⁷⁷

alter iterator

Is this interesting at all ?

```
1  from my_iterators import alter
2
3  for a in alter():
4      print(a)
5      if a >= 6:
6          break
7
8  # 1
9  # -2
10 # 3
11 # -4
12 # 5
13 # -6
14 # 7
```

Create a counter queue

³⁷⁵<http://stackoverflow.com/questions/100003/what-is-a-metaclass-in-python>

³⁷⁶<http://intermediatepythonista.com/classes-and-objects-ii-descriptors>

³⁷⁷<https://docs.python.org/howto/descriptor.html>

```
1  import threading
2  import Queue
3
4  class ThreadedCount(threading.Thread):
5      def __init__(self, name, start, stop):
6          threading.Thread.__init__(self)
7          self.name = name
8          self.counter = start
9          self.limit = stop
10     def run(self):
11         while self.counter < self.limit:
12             self.counter += 1
13             print(self.name, self.counter)
14
15         print(self.name, "finished")
16         return
17
18 queue = Queue()
19 foo = ThreadedCount("Foo", 1, 10)
20 bar = ThreadedCount("Bar", 1, 10)
21 foo.start()
22 bar.start()
23 print("main - running")
24
25 foo.join()
26 bar.join()
27 print("main - thread is done")
```

A Queue of tasks

```
1  from queue import Queue
2  from threading import Thread
3
4  def source():
5      """Returning the list of tasks"""
6      return range(1, 10)
7
8  def do_work(item):
9      print("Working on item " + str(item) + "\n", end="")
10     # print("Working on item ", str(item))
11     # would show the output intermingled as the separate items of the print statement
12     # (even the trailing newline) might be printed only after context switch
```

```
13
14
15 def worker():
16     while True:
17         item = q.get()
18         do_work(item)
19         q.task_done()
20
21 def main():
22     for i in range(num_worker_threads):
23         t = Thread(target=worker)
24         t.daemon = True
25         t.start()
26
27     for item in source():
28         q.put(item)
29
30     q.join()      # block until all tasks are done
31
32 num_worker_threads = 3
33 q = Queue()
34 main()
```

Filtered Fibonacci with ifilter

```
1 from series import fibonacci
2 from itertools import ifilter
3
4 even = ifilter( lambda f: f % 2 == 0, fibonacci() )
5 for e in even:
6     print(e)
7     if e > 200:
8         break
```

Python from .NET

TODO and add to dotnet

TODO: example with async call in .NET getting back to python
